Milgram’s use of deception and stress triggered a debate over his research ethics. In his own defense, Milgram pointed out that, after the participants learned of the deception and actual research purposes, virtually none regretted taking part (though perhaps by then the participants had reduced their cognitive dissonance—the discomfort they felt when their actions conflicted with their attitudes). When 40 of the teachers who had agonized most were later interviewed by a psychiatrist, none appeared to be suffering emotional aftereffects. All in all, said Milgram, the experiments provoked less enduring stress than university students experience when facing and failing big exams (Blass, 1996). Other scholars, however, after delving into Milgram’s archives, report that his debriefing was less extensive and his participants’ distress greater than he had suggested (Nicholson, 2011; Perry, 2013). Critics have also speculated that participants may have been identifying with the researcher and his scientific goals rather than being blindly obedient (Haslam et al., 2014, 2016).

In later experiments, Milgram discovered some conditions that influence people’s behavior. When he varied the situation, full obedience ranged from 0 to 93 percent. Obedience was highest when

- *the person giving the orders was close at hand and was perceived to be a legitimate authority figure.* Such was the case in 2005 when Temple University’s basketball coach sent a 250-pound bench player, Nehemiah Ingram, into a game with instructions to commit “hard fouls.” Following orders, Ingram fouled out in four minutes after breaking an opposing player’s right arm.

- *the authority figure was supported by a powerful or prestigious institution.* Compliance was somewhat lower when Milgram dissociated his experiments from Yale University. People have wondered: Why, during the 1994 Rwandan genocide, did so many Hutu citizens slaughter their Tutsi neighbors? It was partly because they were part of “a culture in which orders from above, even if evil,” were understood as having the force of law (Kamatali, 2014).
- *the victim was depersonalized or at a distance, even in another room.* Similarly, many soldiers in combat either have not fired their rifles at an enemy they could see, or have not aimed them properly. Such refusals to kill are rarer among soldiers operating long-distance artillery or aircraft weapons (Padgett, 1989). Those who kill from a distance—by operating remotely piloted drones—also suffer much less posttraumatic stress than do veterans of on-the-ground conflict (Miller, 2012a).
- *there were no role models for defiance.* “Teachers” did not see any other participant disobey the experimenter.

Stanley Milgram (1933–1984)

This social psychologist's obedience experiments “belong to the self-understanding of literate people in our age” (Sabini, 1986).

The power of legitimate, close-at-hand authorities was apparent among those who followed orders to carry out the Nazis' Holocaust atrocities.

Obedience alone does not explain the Holocaust—anti-Semitic ideology produced eager killers as well (Fenigstein, 2015; Mastroianni, 2015). But obedience was a factor. In the summer of 1942, nearly 500 middle-aged German reserve police officers were dispatched to German-occupied Jozefow, Poland. On July 13, the group’s visibly upset commander informed his recruits, mostly family men, of their orders. They were to round up the village’s Jews, who were said to be aiding the enemy. Able-bodied men would be sent to work camps, and the rest would be shot on the spot.

The commander gave the recruits a chance to refuse to participate in the executions. Only about a dozen immediately refused. Within 17 hours, the remaining 485 officers killed 1500 helpless women, children, and elderly, shooting them in the back of the head as they lay face down. Hearing the victims’ pleas, and seeing the gruesome results, some 20 percent of the officers did eventually dissent, managing either to miss their victims or to slip away and hide until the slaughter was over (Browning, 1992). In real life, as in Milgram’s experiments, those who resisted usually did so early, and they were the minority.

A different story played out in the French village of Le Chambon. There, villagers openly defied orders to cooperate with the “New Order”: They sheltered French Jews destined for deportation to Germany, and they sometimes helped them escape across the Swiss border. The villagers’ Protestant ancestors had themselves been persecuted, and their pastors taught them to “resist whenever our adversaries will demand of us obedience contrary to the orders of the Gospel” (Rochat, 1993). Ordered by police to give a list of sheltered Jews, the head pastor modeled defiance: “I don’t know of Jews, I only know of human beings.” At great personal risk, the people of Le Chambon made an initial commitment to resist. Throughout the long and terrible war, they suffered poverty and were punished for their disobedience. Still, supported by their beliefs, their role models, their interactions with one another, and their own initial acts, they remained defiant to the war’s end.

Lest we presume that obedience is always evil and resistance is always good, consider the heroic obedience of British soldiers who, in 1852, were traveling with civilians aboard the steamship *Birkenhead*. As they neared their South African port, the *Birkenhead* became impaled on a rock. To calm the passengers and permit an orderly exit of civilians on the three available lifeboats, soldiers who were not assisting the passengers or working the

pumps lined up at parade rest. “Steady, men!” said their officer as the lifeboats pulled away. Heroically, no one frantically rushed to claim a lifeboat seat. As the boat sank, all were plunged into the sea, most to be drowned or devoured by sharks. For almost a century, noted James Michener (1978), “the Birkenhead drill remained the measure by which heroic behavior at sea was measured.”

Jeff Widener/AP Photo

Standing up for democracy

Some individuals—roughly one in three in Milgram’s experiments—resist social coercion, as did this unarmed man in Beijing, by single-handedly challenging an advancing line of tanks the day after the 1989 Tiananmen Square student uprising was suppressed.

Lessons From the Conformity and Obedience Studies

LOQ 13-5 What do the social influence studies teach us about ourselves? How much power do we have as individuals?

How do the laboratory experiments on social influence relate to everyday life? How does judging the length of a line or flicking a shock switch relate to everyday social behavior? Psychology’s experiments aim not to re-create the literal behaviors of everyday life but to capture and explore the underlying processes that shape those behaviors. Solomon Asch and Stanley Milgram

devised experiments that forced a familiar choice: Do I adhere to my own standards, even when they conflict with the expectations of others?

In Milgram's experiments and their modern replications, participants were torn. Should they respond to the pleas of the victim or the orders of the experimenter? Their moral sense warned them not to harm another, yet it also prompted them to obey the experimenter and to be a good research participant. With kindness and obedience on a collision course, obedience usually won.

These experiments demonstrated that strong social influences can make people conform to falsehoods or capitulate to cruelty. Milgram saw this as the fundamental lesson of this work: "Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process" (1974, [p. 6](#)).

"I was only following orders."

Adolf Eichmann, Director of Nazi deportation of Jews to concentration camps

Focusing on the end point—450 volts, or someone's real-life violence—we can hardly comprehend the inhumanity. But Milgram did not entrap his teachers by asking them first to zap learners with enough electricity to make their hair stand on end. Using the foot-in-the-door technique, he instead began with a little tickle of electricity and escalated step by step. In the minds of those throwing the switches, the small action became justified, making the next act tolerable. So it happens when people succumb, gradually, to evil.

In any society, great evils often grow out of people's compliance with lesser evils. The Nazi leaders suspected that most German civil servants would resist shooting or gassing Jews directly, but they found them surprisingly willing to handle the paperwork of the Holocaust (Silver & Geller, 1978). Milgram found a similar reaction in his experiments. When he asked 40 men to administer the learning test while someone else did the shocking, 93 percent complied. Cruelty does not require devilish villains. All it takes is ordinary people corrupted by an evil situation. Ordinary students may follow orders to haze initiates into their group. Ordinary employees may follow orders to produce and market harmful products. Ordinary soldiers may follow orders to punish and then torture prisoners (Lankford, 2009).

In Jozefow and Le Chambon, as in Milgram's experiments, those who resisted usually did so early. After the first acts of compliance or resistance, attitudes began to follow and justify behavior.

What have social psychologists learned about the power of the individual? *Social control* (the power of the situation) and *personal control* (the power of the individual) interact. Much as water dissolves salt but not sand, so rotten situations turn some people into bad apples while others resist (Johnson, 2007).

“All evil begins with 15 volts.”

Philip Zimbardo, Stanford lecture, 2010

Some people do resist. When feeling pressured, some react by doing the opposite of what is expected (Brehm & Brehm, 1981). The power of one or two individuals to sway majorities is *minority influence* (Moscovici, 1985). In studies, one finding repeatedly stands out. When you are the minority, you are far more likely to sway the majority if you hold firmly to your position and don't waffle. This tactic won't make you popular, but it may make you influential, especially if your self-confidence stimulates others to consider why you react as you do. Even when a minority's influence is not yet visible, people may privately develop sympathy for the minority position and rethink their views (Wood et al., 1994).

The powers of social influence are enormous, but so are the powers of the committed individual. Were this not so, communism would have remained an obscure theory, Christianity would be a small Middle Eastern sect, and Rosa Parks' refusal to sit at the back of the bus would not have ignited the U.S. civil rights movement. Social forces matter. But individuals matter, too.

RETRIEVAL PRACTICE

RP-5 Psychology's most famous obedience experiments, in which most participants obeyed an authority figure's demands to inflict presumed painful, dangerous shocks on an innocent participant, were conducted by social psychologist_____.

ANSWER: Stanley Milgram.

RP-6 What situations have researchers found to be most likely to encourage obedience in participants?

ANSWER: The Milgram studies showed that people were most likely to follow orders when the experimenter was nearby and perceived to be a legitimate authority figure, the victim was not nearby, and there were no models for defiance.

Sueddeutsche Zeitung Photo/Alamy

A minority of one

To be August Landmesser, standing defiantly with arms folded as everyone else salutes their allegiance to the Nazi Party and Adolph Hitler, requires extraordinary courage. But sometimes such individuals have inspired others, demonstrating the power of minority influence.

Group Behavior

LOQ 13-6 How does the presence of others influence our actions, via social facilitation, social loafing, and deindividuation?

Imagine standing in a room holding a fishing pole. Your task is to wind the reel as fast as you can. On some occasions you wind in the presence of

another participant, who is also winding as fast as possible. Will the other’s presence affect your own performance?

In one of social psychology’s first experiments, Norman Triplett (1898) reported that adolescents would wind a fishing reel faster in the presence of someone doing the same thing. Although a modern reanalysis revealed that the difference was modest (Stroebe, 2012), Triplett inspired later social psychologists to study how others’ presence affects our behavior. Group influences operate both in simple groups—one person in the presence of another—and in more complex groups.

Social Facilitation

Triplett’s claim—of strengthened performance in others’ presence—is called [social facilitation](#). But further studies revealed that the truth is more complicated: The presence of others strengthens our most *likely* response—the correct one on an easy task, an incorrect one on a difficult task (Guerin, 1986; Zajonc, 1965). Why? Because when others observe us, we become aroused, and this arousal amplifies our reactions. Thus, expert pool players who made 71 percent of their shots when alone made 80 percent when four people came to watch them (Michaels et al., 1982). Poor shooters, who made 36 percent of their shots when alone, made only 25 percent when watched.

social facilitation improved performance on simple or well-learned tasks in the presence of others.

The energizing effect of an enthusiastic audience helps explain the home-team advantage that has shown up in studies of more than a quarter-million college and professional athletic events in various countries (Allen & Jones, 2014; Jamieson, 2010). Home teams win about 6 in 10 games, with the home advantage being greatest for teamwork-centered sports, such as soccer and basketball (Jones, 2015). For most sports, home cooking is best (see [TABLE 13.1](#)).

TABLE 13.1

Home Advantage in Team Sports

Sport	Years	Percentage of home games won
Nippon League Baseball	1998–2009	53.6
Major League Baseball	1903–2009	53.9
National Hockey League	1917–2009	55.7
International Rugby	1871–2009	56.9
National Football League	1966–2009	57.3
International Cricket	1877–2009	57.4
National Basketball Association	1946–2009	60.5
Women's National Basketball Association	2003–2009	61.7
English Premier League Soccer	1993–2009	63.0
NCAA Men's Basketball	1947–2009	68.8
Major League Soccer	2002–2009	69.1

Data from Moskowitz & Wertheim, 2011.

The point to remember: What you do well, you are likely to do even better in front of an audience, especially a friendly audience. What you normally find difficult may seem all but impossible when you are being watched.

Social facilitation also helps explain a funny effect of crowding. Comedians know that a “good house” is a full one. What they may not know is that crowding triggers arousal. Comedy routines that are mildly amusing in an uncrowded room seem funnier in a densely packed room (Aiello et al., 1983; Freedman & Perlick, 1979). When seated close to one another, people like a friendly person even more and an unfriendly person even less

(Schiffenbauer & Schiavo, 1976; Storms & Thomas, 1977). So, to increase the chances of a lively interaction at your next event, choose a room or set up seating that will just barely accommodate everyone.

Social Loafing

Social facilitation experiments test the effect of others' presence on the performance of an individual task, such as shooting pool. But what happens when people perform as a group—say, in a team tug-of-war? Would you exert more, less, or the same effort as in a one-on-one match?

To find out, a University of Massachusetts research team asked blindfolded students “to pull as hard as you can” on a rope. When they fooled the students into believing three others were also pulling behind them, students exerted only 82 percent as much effort as when they knew they were pulling alone (Ingham et al., 1974). And consider what happened when blindfolded people seated in a group clapped or shouted as loudly as they could while hearing (through headphones) other people clapping or shouting loudly (Latané, 1981). When they thought they were part of a group effort, the participants produced about one-third less noise than when clapping or shouting “alone.”

Hope College

Social facilitation

Skilled athletes often find they are “on” before an audience. What they do well, they do even better when people are watching.

This diminished effort is called [social loafing](#) (Jackson & Williams, 1988; Latané, 1981). Experiments in the United States, India, Thailand, Japan, China, and Taiwan have found social loafing on various tasks, though it was especially common among men in individualist cultures (Karau & Williams, 1993). What causes social loafing? When people act as part of a group, they may

social loafing the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable.

- feel *less accountable* and therefore worry less about what others think.

- view their individual contributions as *dispensable* (Harkins & Szymanski, 1989; Kerr & Bruun, 1983).
- *overestimate* their own contributions, neglecting others' actions (Schroeder et al., 2016).
- slack off (as you perhaps have observed on group assignments) if they share equally in the benefits, regardless of how much they contribute. Unless highly motivated and strongly identified with the group, people may *free ride* on others' efforts.

Deindividuation

We've seen that the presence of others can arouse people (social facilitation), or it can diminish their feelings of responsibility (social loafing). But sometimes the presence of others does both. The uninhibited behavior that results can range from a food fight to vandalism or rioting. This process of losing self-awareness and self-restraint, called [deindividuation](#), often occurs when group participation makes people both *aroused* and *anonymous*. Compared with identifiable women in a control group, New York University women dressed in depersonalizing Ku Klux Klan-style hoods delivered twice as much presumed electric shock to a victim (Zimbardo, 1970).

deindividuation the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity.

Deindividuation thrives, for better or for worse, in many settings. The anonymity of online discussion boards and blog comment sections can unleash mocking or cruel words. Online bullies, who would never say “You’re the ugliest person I know” to someone’s face, will hide behind their anonymity. Tribal warriors who depersonalize themselves with face paints or masks are more likely than those with exposed faces to kill, torture, or mutilate captured enemies (Watson, 1973). When we shed self-awareness and self-restraint—whether in a mob, at a rock concert, at a ballgame, or at worship—we become more responsive to the group experience—bad or good. For a comparison of social facilitation, social loafing, and deindividuation, see [TABLE 13.2](#).

TABLE 13.2

Behavior in the Presence of Others: Three Phenomena

Phenomenon	Social context	Psychological effect of others' presence	Behavioral effect
<i>Social facilitation</i>	Individual being observed	Increased arousal	Amplified dominant behavior, such as doing better what one does well (or doing worse what is difficult)
<i>Social loafing</i>	Group projects	Diminished feelings of responsibility when not individually accountable	Decreased effort
<i>Deindividuation</i>	Group setting that fosters arousal and anonymity	Reduced self-awareness	Lowered self-restraint

* * *

We have examined the conditions under which the *presence* of others can motivate people to exert themselves or tempt them to free ride on the efforts of others, make easy tasks easier and difficult tasks harder, and enhance humor or fuel mob violence. Research also shows that *interacting* with others can similarly have both bad and good effects.

Lewis Whyld/ PA Wire/AP Images

Deindividuation

During England's 2011 riots and looting, rioters were disinhibited by social arousal and by the anonymity provided by darkness and their hoods and masks. Later, some of those arrested expressed bewilderment over their own behavior.

Group Polarization

LOQ 13-7 How can group interaction enable group polarization?

We live in an increasingly polarized world. The Middle East is torn by warring factions. The European Union is struggling with nationalist divisions. In 1990, a one-minute speech in the U.S. Congress would enable you to guess the speaker's party just 55 percent of the time; by 2009, partisanship was evident 83 percent of the time (Gentzkow et al., 2016). In 2016, for the first time in survey history, most U.S. Republicans and Democrats reported having "very unfavorable" views of the other party (Doherty & Kiley, 2016). And a record 77 percent of Americans perceived their nation as divided (Jones, 2016).

A powerful principle helps us understand our increasingly polarized world: The beliefs and attitudes we bring to a group grow stronger as we discuss them with like-minded others. This process, called **group polarization**, can have beneficial results, as when low-prejudice students become even more accepting while discussing racial issues. And it can be socially toxic, as when high-prejudice students who discuss racial issues become more prejudiced (Myers & Bishop, 1970; [FIGURE 13.4](#)). Our repeated finding: Like minds polarize.

group polarization the enhancement of a group's prevailing inclinations through discussion within the group.

FIGURE 13.4 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers
Data from Myers & Bishop, 1970

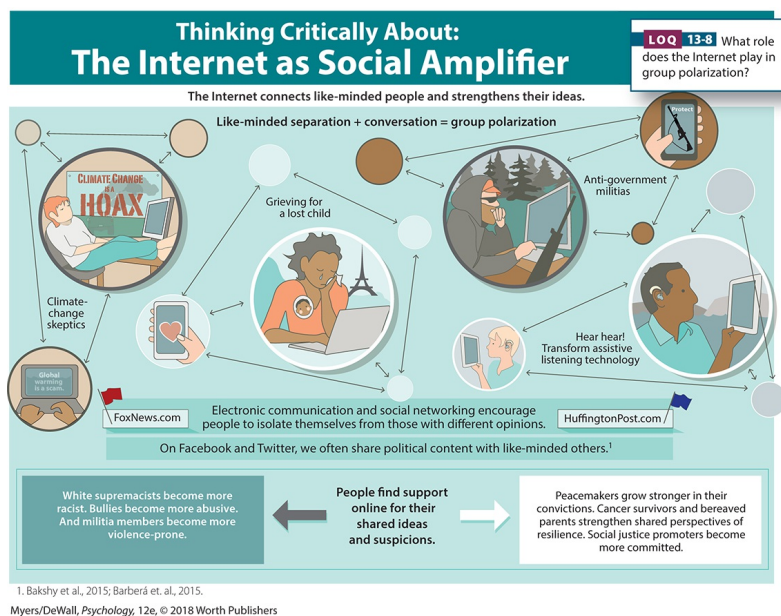

FIGURE 13.4 Group polarization

If a group is likeminded, discussion strengthens its prevailing opinions. Talking over racial issues increased prejudice in a high-prejudice group of high school students and decreased it in a low-prejudice group.

Analyses of terrorist organizations reveal that the terrorist mentality emerges slowly, among people who share a grievance (McCauley, 2002; McCauley & Segal, 1987; Merari, 2002). As they interact in isolation (sometimes with other “brothers” and “sisters” in camps or in prisons), their views grow more and more extreme. Increasingly, they categorize the world as “us” against “them” (Chulov, 2014; Moghaddam, 2005). Knowing that group polarization occurs when like-minded people segregate, a 2006 U.S. National Intelligence estimate speculated that “the operational threat from self-radicalized cells will grow.”

The Internet offers us a connected global world, yet also provides an easily accessible medium for group polarization. When I [DM] got my start in social psychology with experiments on group polarization, I never imagined the potential dangers, or the creative possibilities, of polarization in

virtual groups. Progressives friend progressives and share links to sites that affirm their shared views. Conservatives connect with conservatives and likewise share conservative perspectives. With news feeds and retweets, we feed one another information—and misinformation—and click on content we agree with (Bakshy et al., 2015; Barberá et al., 2015). Thus, within the Internet’s echo chamber of the like-minded, views become more extreme. Suspicion becomes conviction. Disagreements with the other tribe can escalate to demonization. (For more on the Internet’s role in group polarization—toward ends that are good as well as bad—see Thinking Critically About: The Internet as Social Amplifier.)

“Dear Satan, thank you for having my Internet news feeds tailored especially for ME!”

Comedian Steve Martin, 2016 tweet

Groupthink

LOQ 13-9 How can group interaction enable groupthink?

Does group influence ever distort important national decisions? Consider the Bay of Pigs fiasco. In 1961, U.S. President John F. Kennedy and his advisers decided to invade Cuba with 1400 CIA-trained Cuban exiles. When the

invaders were easily captured and quickly linked to the U.S. government, Kennedy wondered aloud, “How could I have been so stupid?”

Social psychologist Irving Janis (1982) studied the decision-making process leading to the ill-fated invasion. He discovered that the soaring morale of the recently elected president and his advisers fostered undue confidence. To preserve the good feeling, group members suppressed or self-censored their dissenting views, especially after President Kennedy voiced his enthusiasm for the scheme. Since no one spoke strongly against the idea, everyone assumed the support was unanimous. To describe this harmonious but unrealistic group thinking, Janis coined the term [groupthink](#).

groupthink the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives.

Later studies showed that groupthink—fed by overconfidence, conformity, self-justification, and group polarization—contributed to other fiascos as well. Among them were the failure to anticipate the 1941 Japanese attack on Pearl Harbor; the escalation of the Vietnam war; the U.S. Watergate cover-up; the Chernobyl nuclear reactor accident (Reason, 1987); the U.S. space shuttle *Challenger* explosion (Esser & Lindorfer, 1989); and the Iraq war, launched on the false idea that Iraq had weapons of mass destruction (U.S. Senate Intelligence Committee, 2004).

“One of the dangers in the White House, based on my reading of history, is that you get wrapped up in groupthink and everybody agrees with everything, and there’s no discussion and there are no dissenting views.”

Barack Obama, December 1, 2008, press conference

Despite the dangers of groupthink, two heads are often better than one. Knowing this, Janis also studied instances in which U.S. presidents and their advisers collectively made good decisions, such as when the Truman administration formulated the Marshall Plan, which offered assistance to Europe after World War II, and when the Kennedy administration

successfully prevented the Soviets from installing missiles in Cuba. His conclusion? Groupthink is prevented when a leader—whether in government or in business—welcomes various opinions, invites experts’ critiques of developing plans, and assigns people to identify possible problems. Just as the suppression of dissent bends a group toward bad decisions, open debate often shapes good ones. This is especially the case with diverse groups, whose varied perspectives often enable creative or superior outcomes (Nemeth & Ormiston, 2007; Page, 2007). Teams of smart people tend to surpass individual smart people at predicting political events (Mellers et al., 2015). None of us is as smart as all of us.

“If you have an apple and I have an apple and we exchange apples then you and I will still each have one apple. But if you have an idea and I have an idea and we exchange these ideas, then each of us will have two ideas.”

Attributed to dramatist George Bernard Shaw, 1856–1950

RETRIEVAL PRACTICE

RP-7 What is social facilitation, and why is it more likely to occur with a well-learned task?

ANSWER: This improved performance in the presence of others is most likely to occur with a well-learned task, because the added arousal caused by an audience tends to strengthen the most likely response. This also predicts poorer performance on a difficult task in others’ presence.

RP-8 People tend to exert less effort when working with a group than they would alone, which is called

_____.
ANSWER: social loafing.

RP-9 You are organizing a meeting of fiercely competitive political candidates. To add to the fun, friends have suggested handing out masks of the candidates’ faces for supporters to wear. What phenomenon might these masks engage?

ANSWER: The anonymity provided by the masks, combined with the arousal of the contentious setting, might create deindividuation (lessened self-awareness and self-restraint).

RP-10 When like-minded groups discuss a topic, and the result is the strengthening of the prevailing opinion, this is called _____.

ANSWER: group polarization.

RP-11 When a group's desire for harmony overrides its realistic analysis of other options, _____ has occurred.

ANSWER: groupthink

REVIEW Social Influence

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answers—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Researchers have found that a person is most likely to conform to a group if

- a. the group members have diverse opinions.
- b. the person feels competent and secure.
- c. the person admires the group's status.
- d. no one else will observe the person's behavior.

In Milgram's experiments, the rate of compliance was highest when

- a. the "learner" was at a distance from the "teacher."
- b. the "learner" was close at hand.
- c. other "teachers" refused to go along with the experimenter.
- d. the "teacher" disliked the "learner."

Dr. Huang, a popular music professor, delivers fascinating lectures on music history but gets nervous and makes mistakes when describing exam statistics in front of the class. Why does his performance vary by task?

In a group situation that fosters arousal and anonymity, a person sometimes loses self-consciousness and self-control. This phenomenon is called _____.

Sharing our opinions with like-minded others tends to strengthen our views, a phenomenon referred to as _____.

Answers are a click away in the e-book, and available in [Appendix D](#), at the back of the printed text.

Use  **LearningCurve** to create your personalized study plan, which will direct you to the Macmillan resources that will help you most.

Antisocial Relations

Social psychology studies how we think about and influence one another, and also how we *relate* to one another. What causes people sometimes to hate and harm, and other times to love and help one another? And when destructive conflicts arise, how can we move toward a just peace? In this section we ponder insights into *antisocial* relations gleaned by researchers who have studied prejudice and aggression.

Prejudice

LOQ 13-10 What is *prejudice*? How do explicit and implicit prejudice differ?

Prejudice means “prejudgment.” It is an unjustifiable and usually negative *attitude* toward a group and its members—who often are people of a particular racial or ethnic group, gender, sexual orientation, or belief system. You may recall that *attitudes* are feelings, influenced by beliefs, that predispose us to act in certain ways. In prejudice, the ingredients in this three-part mixture are

prejudice an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action.

- *negative emotions*, such as hostility or fear.
- **stereotypes**, which are generalized beliefs about a group of people. Our stereotypes sometimes reflect reality. If you presume that young men tend to drive faster than elderly women, you may be right. But stereotypes often overgeneralize or exaggerate—as when liberals and conservatives overestimate the extremity of the other’s views, or Christians and atheists misperceive each other’s values (Graham et al., 2012; Simpson & Rios,

2016).

- a predisposition to **discriminate**—to act in negative and unjustifiable ways toward members of the group. Sometimes prejudice is blatant. Other times it is more subtle, taking the form of *microaggressions*, such as race-related traffic stops, a reluctance to choose a train seat next to someone of a different race, or longer Uber wait times and less Airbnb acceptance for people with African-American names (Edelman et al., 2017; Ge et al., 2016; Wang et al., 2011).

stereotype a generalized (sometimes accurate but often overgeneralized) belief about a group of people.

discrimination unjustifiable negative behavior toward a group and its members.

Prejudice is a negative *attitude*. To believe that obese people are gluttonous, and to feel dislike for an obese person, is to be prejudiced. Discrimination is a negative *behavior*. To pass over obese people on a dating site, or to reject an obese job candidate, is to discriminate.

“We’re also guarding against the subtle impulse to call Johnny back for a job interview but not Jamal.”

President Barack Obama, funeral for Clementa Pinkney, 2015

KAMIL KRZACZYN SKI//EPA/Newscom

Home-grown terrorism

In the 16 years following the terror of September 11, 2001, many Americans feared attacks from foreign terrorists. Yet since that time, attacks by homegrown White supremacists and other non-Muslim extremists were nearly twice as likely (Shane, 2015)—as when a neo-Nazi slaughtered six people in a 2012 shooting at a Wisconsin Sikh temple.

Explicit and Implicit Prejudice

Again and again, we have seen that our brain processes thoughts, memories, and attitudes on two different tracks. Sometimes that processing is *explicit*—on the radar screen of our awareness. More often, it is *implicit*—an unthinking knee-jerk response operating below the radar, leaving us unaware of how our attitudes are influencing our behavior. In 2015, the U.S. Supreme Court, in upholding the Fair Housing Act, recognized implicit bias research, noting that “unconscious prejudices” can cause discrimination even when people do not consciously intend to discriminate.

Psychologists study implicit prejudice by

- Testing for unconscious group associations: Tests in which people quickly pair a person’s image with a trait demonstrate that even people who deny any racial prejudice may harbor negative associations (Banaji & Greenwald, 2013). Millions of people have taken the Implicit Association Test (as you can, too, at Implicit.Harvard.edu). Although the test is useful for studying automatic prejudice, critics caution against using it to assess or label individuals (Oswald et al., 2013, 2015). Defenders counter that implicit biases predict behaviors ranging from simple acts of friendliness to the evaluation of work quality (Greenwald et al., 2015).
- Considering unconscious patronization: In one experiment, White university women assessed flawed student essays they believed had been written by either a White or a Black student. The women gave low evaluations, often with harsh comments, to the essays supposedly written by a White student. When the same essay was attributed to a Black student, their assessment was more positive (Harber, 1998). Did the evaluators calibrate their evaluations to their racial stereotypes, leading to less exacting standards and a patronizing attitude? In real-world evaluations,

such low expectations and the resulting “inflated praise and insufficient criticism” could hinder minority student achievement, the researcher noted.

- **Monitoring reflexive bodily responses:** Even people who consciously express little prejudice may give off telltale signals as their body responds selectively to an image of a person from another ethnic group. Neuroscientists can detect signals of implicit prejudice in the viewer’s facial-muscle responses and in the activation of the emotion-processing amygdala (Cunningham et al., 2004; Eberhardt, 2005; Stanley et al., 2008).

Targets of Prejudice

LOQ 13-11 What groups are frequent targets of prejudice?

RACIAL AND ETHNIC PREJUDICE Americans’ expressed racial attitudes have changed dramatically in the last half-century. Support for interracial dating between Blacks and Whites, for example, has increased dramatically, from a 48 percent approval rate in 1987 to 86 percent in 2012 (Pew, 2012; see also [FIGURE 13.5](#)). Similarly, 4 percent of Americans approved of “marriage between Blacks and Whites” in 1958, but 87 percent approved in 2013 (Newport, 2013b). Six in ten Americans—double the number in most European countries—agree that “an increasing number of people of many different races, ethnic groups, and nationalities in our country makes it a better place to live” (Drake & Poushter, 2016).

FIGURE 13.5 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Pew, 2012

FIGURE 13.5 Prejudice over time

Over the last quarter-century, Americans have increasingly approved interracial dating, with each successive generation expressing more approval.

Yet as blatant interracial prejudice wanes, *subtle* prejudice lingers. People with darker skin tones experience greater criticism and accusations of immoral behavior (Alter et al., 2016). In one study of White medical students and residents, 1 in 3 believed “black people’s skin is thicker than white people’s skin,” which led them to make harmful treatment recommendations (Hoffman et al., 2016). And although many people say they would feel upset with someone making racist or homophobic slurs, they respond indifferently when they actually hear prejudice-laden language (Kawakami et al., 2009).

Other studies reveal prejudice that is not just subtle, but unconscious (implicit). For example, in an Implicit Association Test, 9 in 10 White respondents took longer to identify pleasant words (such as *peace* and *paradise*) as “good” when presented with Black-sounding names (such as *Latisha* and *Darnell*) rather than with White-sounding names (such as *Katie* and *Ian*). Moreover, people who more quickly associate good things with White names or faces also are the quickest to perceive anger and apparent threat in Black faces (Hugenberg & Bodenhausen, 2003). In the 2008 U.S. presidential election, those demonstrating explicit or implicit prejudice were less likely to vote for candidate Barack Obama. His election in turn served to reduce implicit prejudice (Bernstein et al., 2010; Payne et al., 2010; Stephens-Davidowitz, 2014).

“Unhappily, the world has yet to learn how to live with diversity.”

Pope John Paul II, Address to the United Nations, 1995

Our perceptions can also reflect implicit bias. In 1999, Amadou Diallo was accosted as he approached his apartment house doorway by police officers looking for a rapist. When he pulled out his wallet, the officers, perceiving a gun, riddled his body with 19 bullets from 41 shots. In one analysis of 59 unarmed suspect shootings in Philadelphia over seven years, 49 involved the misidentification of an object (such as a cell phone) or movement (such as pants tugging). Black suspects were more than twice as likely to be misperceived as threatening, even by Black officers (Blow, 2015). Across the United States, nearly 40 percent of the unarmed people shot and killed by police during 2015 and 2016 were Black (*Washington Post*, 2017).

“If we can’t help our latent biases, we can help our behavior in response to those instinctive reactions, which is why we work to design systems and processes that overcome that very human part of us all.”

U.S. FBI Director James B. Comey, “Hard Truths: Law Enforcement and Race,” 2015

Rex Features via AP Images

When tragedy triggers a national response

Does implicit bias research—which is now being integrated into both police and corporate diversity training programs—help us understand the 2013 death of Trayvon Martin (shown here 7 months before he was killed)? As he walked alone to his father’s fiancée’s house in a gated Florida neighborhood, a suspicious resident started following him. A confrontation led to the unarmed Martin being shot. Martin’s death sparked public outrage related to racism, gun control, and social justice. Commentators wondered: Had Martin been an unarmed White teen, would he have been perceived and treated the same way?

To better understand such tragic shootings of unarmed, innocent people, two research teams simulated the situation (Correll et al., 2007, 2015; Plant & Peruche, 2005; Sadler et al., 2012a). They asked viewers to press buttons quickly to “shoot” or not shoot men who suddenly appeared on screen. Some of the on-screen men held a gun. Others held a harmless object, such as a flashlight or bottle. People (both Blacks and Whites, and police officers) more often shot Black men holding the harmless object. Priming people with a flashed Black face rather than a White face also made them more likely to

misperceive a flashed tool as a gun ([FIGURE 13.6](#)). Fatigue, which diminishes one's conscious control and increases automatic reactions, amplifies racial bias in decisions to shoot (Ma et al., 2013).

FIGURE 13.6 Myers/DeWall, *Psychology*, 12e,

FIGURE 13.6 Race primes perceptions

In experiments by Keith Payne (2006), people viewed (1) a White or Black face, immediately followed by (2) a flashed gun or hand tool, which was then followed by (3) a masking screen. Participants were more likely to misperceive a tool as a gun when it was preceded by a Black rather than White face.

GENDER PREJUDICE Overt gender prejudice has declined sharply. The one-third of Americans who in 1937 told Gallup pollsters that they would vote for a qualified woman whom their party nominated for president soared to 95 percent in 2012 (Jones, 2012; Newport, 1999). Although women worldwide still represent nearly two-thirds of illiterate adults, and 30 percent have experienced intimate partner violence, 65 percent of all people now say it is very important that women have the same rights as men (UN, 2015c; WHO, 2016b; Zainulbhai, 2016b).

Nevertheless, both implicit and explicit gender prejudice and discrimination persist. In Western countries, we pay more to those (usually men) who care for our streets than to those (usually women) who care for our children. Gender bias even applies to beliefs about intelligence: Despite equality between the sexes in intelligence scores, people have tended to perceive their fathers as more intelligent than their mothers (Furnham & Wu, 2008).

Unwanted female infants are no longer left out on a hillside to die of exposure, as was the practice in ancient Greece. Yet the normal male-to-female newborn ratio (105-to-100) hardly explains the world's estimated 163

million (say that number slowly) “missing women” (Hvistendahl, 2011). In many places, sons are valued more than daughters. In India, there are 3.5 times more Google searches asking how to conceive a boy than how to conceive a girl (Stephens-Davidowitz, 2014). With scientific testing that enables sex-selective abortions, some countries are experiencing a shortfall in female births. India’s newborn sex ratio was recently 112 boys for every 100 girls. China’s has been 111 to 100—despite China’s declaring sex-selective abortions—gender genocide—a criminal offense (CIA, 2014). With under-age-20 males exceeding females by 32 million, many Chinese bachelors will be unable to find mates (Zhu et al., 2009). A shortage of women also contributes to increased crime, violence, prostitution, and trafficking of women (Brooks, 2012).

“Until I was a man, I had no idea how good men had it at work. . . . The first time I spoke up in a meeting in my newly low, quiet voice and noticed that sudden, focused attention, I was so uncomfortable that I found myself unable to finish my sentence.”

Thomas Page McBee, 2016, after transitioning from female to male

LGBTQ PREJUDICE In most of the world, gay and lesbian people cannot openly and comfortably disclose who they are and whom they love (Katz-Wise & Hyde, 2012; UN, 2011). Although by 2016 two dozen countries had allowed same-sex marriage, dozens more had laws criminalizing same-sex relationships. But cultural variation is enormous—ranging from the 98 percent in Ghana who say that “homosexuality is morally unacceptable” to 6 percent in Spain (Pew, 2014b). Worldwide, anti-gay attitudes are most common among men, older adults, and those who are unhappy, unemployed, and less educated (Haney, 2016; Jäckle & Wenzelburger, 2015).

Explicit anti-gay prejudice, though declining in Western countries, persists. When experimenters sent thousands of responses to employment ads, those whose resumes included “Treasurer, Progressive and Socialist Alliance” received more replies than did resumes that specified “Treasurer, Gay and Lesbian Alliance (Agerström et al., 2012; Bertrand & Mullainathan, 2003; Drydakis, 2009). Other evidence has appeared in national surveys of LGBTQ Americans:

- 39 percent reported having been “rejected by a friend or family member” because of their sexual orientation or gender identity (Pew, 2013c).
- 58 percent reported being “subject to slurs or jokes” (Pew, 2013c).
- 80 percent of LGBTQ adolescents reported sexual orientation-related harassment in the prior year (GLSEN, 2012). Gays and lesbians are also America’s most at-risk group for hate crimes (Sherman, 2016).

Do attitudes and practices that label, disparage, and discriminate against gay and lesbian people increase their risk of psychological disorder and ill health? In U.S. states without protections against LGBTQ hate crime and discrimination, gay and lesbian people experience substantially higher rates of depression and related disorders, even after controlling for income and education differences. In communities where anti-gay prejudice is high, so are gay and lesbian suicide and cardiovascular deaths. In 16 states that banned same-sex marriage between 2001 and 2005, gays and lesbians (but not heterosexuals) experienced a 37 percent increase in depressive disorder rates, a 42 percent increase in alcohol use disorder, and a 248 percent increase in generalized anxiety disorder. Meanwhile, gays and lesbians in other states did not experience increased psychiatric disorders (Hatzenbuehler, 2014).

BELIEF SYSTEMS PREJUDICE In the aftermath of the 9/11 terrorist attacks and the Iraq and Afghanistan wars, 4 in 10 Americans acknowledged “some feelings of prejudice against Muslims,” and about half of non-Muslims in Western Europe and the United States perceived Muslims as “violent” (Saad, 2006; Wike & Grim, 2007). With many Americans feeling threatened by Arab Muslims, and as opposition to Islamic mosques and immigration flared in 2010, one observer noted that “Muslims are one of the last minorities in the United States that it is still possible to demean openly” (Kristof, 2010; Lyons et al., 2010).

Roots of Prejudice

LOQ 13-12 What are some social, emotional, and cognitive roots of prejudice, and what are some ways to eliminate prejudice?

Prejudice springs from a culture’s divisions, the heart’s passions, and the

mind's natural workings.

SOCIAL INEQUALITIES AND DIVISIONS When some people have money, power, and prestige and others do not, the “haves” usually develop attitudes that justify things as they are. The **just-world phenomenon** reflects an idea we commonly teach our children—that good is rewarded and evil is punished. From this it is but a short leap to assume that those who succeed must be good and those who suffer must be bad. Such reasoning enables the rich to see both their own wealth and the poor's misfortune as justly deserved. When slavery existed in the United States, slaveholders perceived slaves as innately lazy, ignorant, and irresponsible—as having the very traits that justified enslaving them. Stereotypes rationalize inequalities.

just-world phenomenon the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get.

Victims of discrimination may react with either self-blame or anger (Allport, 1954). Either reaction can feed others' prejudice through the classic *blame-the-victim* dynamic. Do the circumstances of poverty breed a higher crime rate? If so, that higher crime rate can be used to justify discrimination against those who live in poverty.

Robert Mankoff The New Yorker Collection/
The Cartoon Bank

Dividing the world into “us” and “them” can entail conflict, racism, and war, but it also provides the benefits of communal solidarity. Thus, we cheer for our groups, kill for them, die for them. Indeed, we define who we are—our *social identity*—partly in terms of our groups (Greenaway et al., 2016; Hogg, 1996, 2006; Turner, 1987, 2007). When Ian identifies himself as a

man, an Aussie, a University of Sydney student, a Catholic, and a MacGregor, he knows who he is, and so do we. Mentally drawing a circle defines “us,” the **ingroup**. But the social definition of who we are also states who we are not. People outside that circle are “them,” the **outgroup**. An **ingroup bias**—a favoring of our own group—soon follows. In experiments, people have favored their own group (arbitrarily created by a simple coin toss) when dividing rewards (Tajfel, 1982; Wilder, 1981). Outside the lab, discrimination is often triggered not by outgroup hostility but by ingroup networking and mutual support, such as hiring a friend’s child at the expense of other candidates (Greenwald & Pettigrew, 2014).

ingroup “us”—people with whom we share a common identity.

outgroup “them”—those perceived as different or apart from our ingroup.

ingroup bias the tendency to favor our own group.

Mike Hewitt/Getty Images

The ingroup

Scotland’s famed “Tartan Army” soccer fans, shown here during a match against archrival England, share a social identity that defines “us” (the Scottish ingroup) and “them” (the English outgroup).

We have inherited our Stone Age ancestors’ need to belong, to live and love in groups. There was safety in solidarity: Whether hunting, defending, or attacking, 10 hands were better than 2. Evolution prepared us, when encountering strangers, to make instant judgments: friend or foe? This urge to distinguish enemies from friends, and to “otherize” as different those not like

us, predisposes prejudice against strangers (Whitley, 1999). To Greeks of the classical era, all non-Greeks were “barbarians.” In our own era, most children believe their school is better than all other schools in town. Many high school students form cliques—jocks (sorted by sport), gangsters, preps, nerds—and disparage those outside their own group. Even chimpanzees have been seen to wipe clean the spot where they were touched by a chimpanzee from another group (Goodall, 1986). They also display ingroup empathy by yawning more after seeing ingroup (rather than outgroup) members yawn (Campbell & de Waal, 2011). An ideal world might equally prioritize justice and love for all. But in our real world, ingroup love often outranks universal justice.

“For if [people were] to choose out of all the customs in the world [they would] end by preferring their own.”

Greek historian Herodotus, 440 B.C.E.

NEGATIVE EMOTIONS Negative emotions nourish prejudice. When facing death, fearing threats, or experiencing frustration, people cling more tightly to their ingroup and their friends. As fears of terrorism heighten patriotism, they also produce loathing and aggression toward “them”—those who threaten our world (Pyszczynski et al., 2002, 2008). [Scapegoat theory](#)

notes that when things go wrong, finding someone to blame can provide a target for our negative emotions. Following the 9/11 attacks, some outraged people lashed out at innocent Arab-Americans. A decade later, anti-Muslim animosities still flared. In 2015, anti-Muslim hate crimes rose 67 percent from the year before (FBI, 2016). And after anti-immigrant sentiments flared in 2016 during the Brexit referendum in Britain and the contentious presidential election in the United States, reports of harassment, bullying, and hate crime rose (Crandall & White, 2016; Hassan, 2016; Kenyon, 2016; North, 2016). “Fear and anger create aggression, and aggression against citizens of different ethnicity or race creates racism and, in turn, new forms of terrorism,” noted Philip Zimbardo (2001).

scapegoat theory the theory that prejudice offers an outlet for anger by providing someone to blame.

“If the Tiber reaches the walls, if the Nile does not rise to the fields, if the sky doesn’t move or the Earth does, if there is famine, if there is plague, the cry is at once: ‘The Christians to the lion!’”

Tertullian, *Apologeticus*, 197 C.E.

Evidence for the scapegoat theory of prejudice comes in two forms: (1) Economically frustrated people tend to express heightened prejudice. (2) Experiments that create temporary frustration intensify prejudice. Students who experience failure or are made to feel insecure often restore their self-esteem by disparaging a rival school or another person (Cialdini & Richardson, 1980; Crocker et al., 1987). Denigrating others may boost our own sense of status, which explains why a rival’s misfortune sometimes provides a twinge of pleasure. (The German language has a word—*Schadenfreude*—for this secret joy that we sometimes take in another’s failure.) By contrast, those made to feel loved and supported become more open to and accepting of others who differ (Mikulincer & Shaver, 2001).

“The misfortunes of others are the taste of honey.”

COGNITIVE SHORTCUTS Stereotyped beliefs are in part a by-product of how we cognitively simplify the world. To help understand the world around us, we sometimes *form categories*. Chemists categorize molecules as organic and inorganic. Therapists categorize psychological disorders. We all categorize people by gender, ethnicity, race, age, and many other characteristics. But when we categorize people into groups, we often stereotype. We recognize how greatly we differ from other individuals in *our* groups. But we overestimate the extent to which members of other groups are alike (Bothwell et al., 1989). We perceive *outgroup homogeneity*—uniformity of attitudes, personality, and appearance. Our greater recognition for individual own-race faces—called the **other-race effect** (or *cross-race effect* or *own-race bias*)—emerges during infancy, between 3 and 9 months of age (Anzures et al., 2013; Telzer et al., 2013). (We also have an *own-age bias*—better recognition memory for faces of our own age group [Rhodes & Anastasi, 2012]).

other-race effect the tendency to recall faces of one's own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias*.

Sometimes, however, people don't fit easily into our racial categories. For example, mixed-race people are often assigned to their minority identity. Researchers believe this happens because, after learning the features of a familiar racial group, the observer's selective attention is drawn to the distinctive features of the less-familiar minority. Jamin Halberstadt and his colleagues (2011) illustrated this learned-association effect by showing New Zealanders blended Chinese-Caucasian faces. Compared with participants of Chinese descent, European-descent New Zealanders more readily classified ambiguous faces as Chinese (see **FIGURE 13.7**). With effort and with experience, people get better at recognizing individual faces from another group (Hugenberg et al., 2010; Young et al., 2012).

FIGURE 13.7 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Dr. Jamin Halberstadt

FIGURE 13.7 Categorizing mixed-race people

When New Zealanders quickly classified 104 photos by race, those of European descent more often than those of Chinese descent classified the ambiguous middle two as Chinese (Halberstadt et al., 2011).

© Dave Coverly/speedbump.com

REMEMBERING VIVID CASES We also simplify our world by employing *heuristics*—mental shortcuts that enable snap judgments. The *availability heuristic* is the tendency to estimate the frequency of an event by how readily it comes to mind. Vivid cases are memorable and they come to mind easily, so it's no surprise that they feed our stereotypes. In a classic experiment, researchers showed two groups of University of Oregon students lists containing information about 50 men (Rothbart et al., 1978). The first group's list included 10 men arrested for *nonviolent* crimes, such as forgery. The second group's list included 10 men arrested for *violent* crimes, such as assault. Later, both groups were asked how many men on their list had committed *any* sort of crime. The second group overestimated the number. Violent crimes form vivid memories (**FIGURE 13.8**).

FIGURE 13.8 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

FIGURE 13.8 Vivid cases feed stereotypes

The 9/11 Muslim terrorists created, in many minds, an exaggerated stereotype of Muslims as terrorism-prone. Actually, reported a U.S. National Research Council panel on terrorism, when offering this inexact illustration, most terrorists are not Muslim and “the vast majority of Islamic people have no connection with and do not sympathize with terrorism” (Smelser & Mitchell, 2002).

To review attribution research and experience a simulation of how stereotypes form, visit **PsychSim 6: Not My Type**. And for a 6.5-minute synopsis of the cognitive and social psychology of prejudice, see the **Video: Prejudice**.

VICTIM BLAMING As we noted earlier, people often justify their prejudices by blaming victims. If the world is just, they assume, people must get what they deserve. As one German civilian is said to have remarked when visiting the Bergen-Belsen concentration camp shortly after World War II, “What terrible criminals these prisoners must have been to receive such treatment.”

Hindsight bias amplifies victim blaming (Carli & Leonard, 1989). Have you ever heard people say that rape victims, abused spouses, or people with AIDS got what they deserved? In some countries, such as Pakistan, rape victims have been sentenced to severe punishment for violating adultery prohibitions (Mydans, 2002). In one experiment, two groups of people were given a detailed account of a date (Janoff-Bulman et al., 1985). The first group’s account reported that the date ended with the woman being raped. Members of that group perceived the woman’s behavior as at least partly to blame, and in hindsight, they thought, “She should have known better.” The second group, given the same account with the rape ending deleted, did not perceive the woman’s behavior as inviting rape. Hindsight bias promoted a blame-the-victim mentality among members of the first group. Blaming the

victim also serves to reassure people that it couldn't happen to them.

People also have a basic tendency to justify their culture's social systems (Jost et al., 2009; Kay et al., 2009). We're inclined to see the way things are as the way they ought to be and deserve to be. If people are rich, they must be smart (Hussak & Cimpian, 2015). This natural conservatism makes it difficult to legislate major social changes, such as health care or climate change policies. Once such policies are in place, our "system justification" tends to preserve them.

RETRIEVAL PRACTICE

RP-12 When prejudiced judgment causes us to blame an undeserving person for a problem, that person is called a _____.

ANSWER: scapegoat

If your own gut-check reveals you sometimes have feelings you would rather not have about other people, remember this: It is what we *do* with our feelings that matters. By monitoring our feelings and actions, and by replacing old habits with new ones based on new friendships, we can work to free ourselves from prejudice.

Aggression

LOQ 13-13 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

Prejudice hurts, but aggression sometimes hurts more. In psychology, **aggression** is any physical or verbal behavior intended to harm someone, whether done out of hostility or as a calculated means to an end. The assertive, persistent salesperson is not aggressive. Nor is the dentist who makes you wince with pain. But the gossip who passes along a vicious rumor about you, the bully who torments you in person or online, and the attacker who mugs you for your money are aggressive.

aggression any physical or verbal behavior intended to harm someone physically or emotionally.

Aggressive behavior emerges from the interaction of biology and experience. For a gun to fire, the trigger must be pulled; with some people, as with hair-trigger guns, it doesn't take much to trip an explosion. Let's look first at some biological factors that influence our thresholds for aggressive behavior, then at the psychological factors that pull the trigger.

Gilbert Laurie/Getty Images

Do guns in the home save or take more lives?

"Personal safety/protection" is the #1 reason U.S. gun owners give for firearm ownership (Swift, 2013). Yet in the last 40 years, well over one million Americans have suffered nonwar firearm deaths—more than all American war deaths. Compared with people of the same sex, race, age, and neighborhood, those who keep a gun in the home have been twice as likely to be murdered and three times as likely to commit suicide (Anglemyer et al., 2014; Stroebe, 2013). States and countries with high gun ownership rates also tend to have high gun death rates (VPC, 2013).

The Biology of Aggression

Aggression varies too widely from culture to culture, era to era, and person to person to be considered an unlearned instinct. But biology does *influence* aggression. We can look for biological influences at three levels—genetic,

neural, and biochemical.

GENETIC INFLUENCES Genes influence aggression. Animals have been bred for aggressiveness—sometimes for sport, sometimes for research. The effect of genes also appears in human twin studies (Miles & Carey, 1997; Rowe et al., 1999). If one identical twin admits to “having a violent temper,” the other twin will often independently admit the same. Fraternal twins are much less likely to respond similarly.

Researchers continue to search for genetic markers in those who commit violent acts. One is already well known and is carried by half the human race: the Y chromosome. Another such marker is the *monoamine oxidase A (MAOA) gene*, which helps break down neurotransmitters such as dopamine and serotonin. Sometimes called the “warrior gene,” people who have low MAOA gene expression tend to behave aggressively when provoked. In one experiment, low (compared with high) MAOA gene carriers gave more unpleasant hot sauce to someone who provoked them (McDermott et al., 2009; Tiihonen et al., 2015).

NEURAL INFLUENCES There is no one spot in the brain that controls aggression. Aggression is a complex behavior, and it occurs in particular contexts. But animal and human brains have neural systems that, given provocation, will either inhibit or facilitate aggression (Falkner et al., 2016; Moyer, 1983; Wilkowski et al., 2011). Consider:

- Researchers implanted a radio-controlled electrode in the brain of the domineering leader of a caged monkey colony. The electrode was in an area that, when stimulated, inhibits aggression. When researchers placed the control button for the electrode in the colony’s cage, one small monkey learned to push it every time the boss became threatening.
- A neurosurgeon, seeking to diagnose a disorder, implanted an electrode in the amygdala of a mild-mannered woman. Because the brain has no sensory receptors, she was unable to feel the stimulation. But at the flick of a switch she snarled, “Take my blood pressure. Take it now,” then stood up and began to strike the doctor.
- Studies of violent criminals have revealed diminished activity in the frontal lobes, which play an important role in controlling impulses. If the frontal lobes are damaged, inactive, disconnected, or not yet fully mature,

aggression may be more likely (Amen et al., 1996; Davidson, 2000; Raine, 2013).

"It's a guy thing."

Donald Reilly The New Yorker Collection/
The Cartoon Bank

BIOCHEMICAL INFLUENCES Our genes engineer our individual nervous systems, which operate electrochemically. The hormone testosterone, for example, circulates in the bloodstream and influences the neural systems that control aggression. A raging bull becomes a gentle giant when castration reduces its testosterone level. Conversely, when injected with testosterone, gentle, castrated mice once again become aggressive.

Humans are less sensitive to hormonal changes. But as men's testosterone levels diminish with age, hormonally charged, aggressive 17-year-olds mature into quieter and gentler 70-year-olds.

Facial width is testosterone-linked. A high facial width-to-height ratio is a predictor of men's aggressiveness and prejudicial attitudes (Carré et al., 2009; Hehman et al., 2013; Stirrat & Perrett, 2010). Women apparently pick up on this by *perceiving* men with higher facial width-to-height ratios as more dominant (Valentine et al., 2014). Other high-testosterone-linked traits among males include irritability, assertiveness, impulsiveness, hard drug use, and low tolerance for frustration (Dabbs et al., 2001; McAndrew, 2009;

Montoya et al., 2012; Olweus et al., 1988). Drugs that sharply reduce testosterone levels subdue men's aggressive tendencies.

“We could avoid two-thirds of all crime simply by putting all able-bodied young men in cryogenic sleep from the age of 12 through 28.”

David T. Lykken, *The Antisocial Personalities*, 1995

Chris Courteau/AGE Fotostock

A lean, mean fighting machine—the testosterone-laden female hyena

The hyena's unusual embryology pumps testosterone into female fetuses. The result is revved-up young female hyenas who seem born to fight.

Another drug that sometimes circulates in the bloodstream—alcohol—*unleashes* aggressive responses to frustration. Across police data, prison surveys, and experiments, aggression-prone people are more likely to drink, and to become violent when intoxicated (White et al., 1993). Alcohol is a disinhibitor—it slows brain activity that controls judgment and inhibitions. Under its influence, people may interpret ambiguous acts (such as being bumped in a crowd) as provocations and react accordingly (Bègue et al., 2010; Giancola & Gorman, 2007). Alcohol has been a factor in 73 percent of homicides in Russia and 57 percent in the United States (Landberg & Norström, 2011).

Just *thinking* you've imbibed alcohol can increase aggression (Bègue et al., 2009). But so, too, does unknowingly ingesting alcohol slipped into a drink. Thus, alcohol affects aggression both biologically and psychologically

(Bushman, 1993; Ito et al., 1996; Taylor & Chermack, 1993).

Psychological and Social-Cultural Factors in Aggression

LOQ 13-14 What psychological and social-cultural factors may trigger aggressive behavior?

Biological factors influence how easily aggression is triggered. But what psychological and social-cultural factors pull the trigger?

AVERSIVE EVENTS Suffering sometimes builds character. In laboratory experiments, however, those made miserable have often made others miserable (Berkowitz, 1983, 1989). Aversive stimuli—hot temperatures, physical pain, personal insults, foul odors, cigarette smoke, crowding—can evoke hostility. A prime example of this phenomenon is the [frustration-aggression principle](#): Frustration creates anger, which can spark aggression.

frustration-aggression principle the principle that frustration—the blocking of an attempt to achieve some goal—creates anger, which can generate aggression.

The frustration-aggression link was illustrated in an analysis of 27,667 hit-by-pitch Major League Baseball incidents between 1960 and 2004 (Timmerman, 2007). Pitchers were most likely to hit batters when they had been frustrated by one of three events: the previous batter had hit a home run; the current batter had hit a home run the last time at bat; or the pitcher's teammate had been hit by a pitch in the previous half inning. A separate study found a similar link between rising temperatures and the number of hit batters (Reifman et al., 1991; see [FIGURE 13.9](#)). When overheated, we think, feel, and act more aggressively.

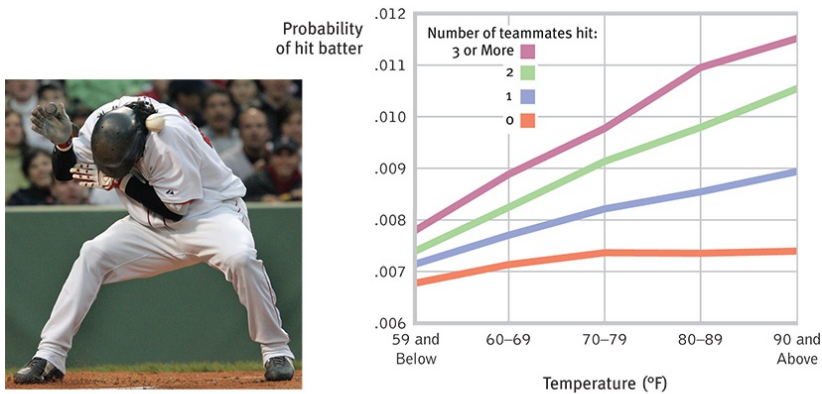

FIGURE 13.9 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Brita Meng Outzen/AP Photo

FIGURE 13.9 Temperature and retaliation

Richard Larrick and his colleagues (2011) looked for occurrences of batters hit by pitchers during 4,566,468 pitcher-batter matchups across 57,293 Major League Baseball games since 1952. The probability of a hit batter increased if one or more of the pitcher's teammates had been hit, and also with temperature.

In the wider world, violent crime and spousal abuse rates have been higher during hotter years, seasons, months, and days (Anderson et al., 1997). Studies from archaeology, economics, geography, political science, and psychology converge in finding that throughout human history, higher temperatures have predicted increased individual violence, wars, and revolutions (Hsiang et al., 2013). Craig Anderson and his colleagues (2000, 2011) have projected that, other things being equal, global warming of 4 degrees Fahrenheit (about 2 degrees Celsius) could induce tens of thousands of additional assaults and murders—and that's before the added violence inducements from climate change-related drought, poverty, food insecurity, and migration.

How have researchers studied these concepts? Learn more by engaging online with **Immersive Learning: How Would You Know If Hot Temperatures Cause Aggression?**

REINFORCEMENT AND MODELING Aggression may naturally follow aversive events, but learning can alter natural reactions. We learn when our behavior is reinforced, and we learn by watching others.

In situations where experience has taught us that aggression pays, we are likely to act aggressively again. Children whose aggression has successfully

intimidated other children may become bullies. Animals that have successfully fought to get food or mates become increasingly ferocious. To foster a kinder, gentler world we had best model and reward sensitivity and cooperation from an early age, perhaps by training parents to discipline without modeling violence.

Parent-training programs often advise parents to avoid modeling violence by screaming and hitting. Instead, parents should reinforce desirable behaviors and frame statements positively. (“When you finish loading the dishwasher you can go play,” rather than “If you don’t load the dishwasher, there’ll be no playing.”)

Different cultures model, reinforce, and evoke different tendencies toward violence. For example, crime rates have also been higher and average happiness lower in times and places marked by a great disparity between rich and poor (Messias et al., 2011; Oishi et al., 2011; Wilkinson & Pickett, 2009). In the United States, cultures and families in which fathers are minimally involved have had high violence rates (Triandis, 1994). Even after controlling for parental education, race, income, and teen motherhood, American male youths from father-absent homes are incarcerated at twice the rate of their peers (Harper & McLanahan, 2004).

Violence can vary by culture within a country. Richard Nisbett and Dov Cohen (1996) analyzed violence among White Americans in southern towns settled by Scots-Irish herders whose tradition emphasized “manly honor,” the use of arms to protect one’s flock, and a history of coercive slavery. Compared with their White counterparts in New England towns settled by the more traditionally peaceful Puritan, Quaker, and Dutch farmer-artisans, the cultural descendants of those herders had triple the homicide rates and were more supportive of physically punishing children, of warfare initiatives, and of uncontrolled gun ownership. “Culture-of-honor” states also had higher rates of students bringing weapons to school and of school shootings (Brown et al., 2009).

MEDIA MODELS FOR VIOLENCE Parents are hardly the only aggression models. In the United States and elsewhere, TV, films, video games, and the Internet offer supersized portions of violence. An adolescent boy faced with a real-life challenge may “act like a man”—at least like an action film man—by intimidating or eliminating the threat. Violent video game playing tends to make us less sensitive to cruelty (Arriaga et al., 2015).

It also primes us to respond aggressively when provoked. And media violence teaches us **social scripts**—culturally provided mental files for how to act in certain situations. As more than 100 studies confirm, we sometimes imitate what we’ve viewed. Watching risk-glorifying behaviors (dangerous driving, extreme sports, unprotected sex) increases real-life risk-taking (Fischer et al., 2011).

social script a culturally modeled guide for how to act in various situations.

Music lyrics also write social scripts. German university men who listened to woman-hating lyrics administered the most hot chili sauce to a woman. They also recalled more negative feelings and beliefs about women. Listening to man-hating lyrics had a similar effect on women (Fischer & Greitemeyer, 2006).

How does repeatedly watching pornographic films affect viewers? As pornography has become more easily available, rates of reported sexual violence have decreased in the United States (though not in Canada, Australia, and Europe). Nevertheless, just as repeated viewing of onscreen violence helps immunize us to aggression, repeated viewing of pornography—even nonviolent pornography—makes sexual aggression seem less serious (Harris, 1994). In one experiment, undergraduates viewed six brief films each week for six weeks (Zillmann & Bryant, 1984). Some viewed sexually explicit films; others viewed films with no sexual content. Three weeks later, both groups, after reading a report about a man convicted of raping a hitchhiker, suggested an appropriate prison term. Compared with sentences recommended by the control group, the sex film viewers recommended terms that were half as long. In other studies that explored pornography’s effects on aggression toward relationship partners, pornography consumption predicted both self-reported aggression and participants’ willingness to administer laboratory noise blasts to their partner (Lambert et al., 2011; Peter & Valkenburg, 2016).

Pornography with violent sexual content can increase men’s readiness to behave aggressively toward women. A statement by 21 social scientists noted, “Pornography that portrays sexual aggression as pleasurable for the victim increases the acceptance of the use of coercion in sexual relations”

(Surgeon General, 1986). Contrary to much popular opinion, viewing such scenes does not provide an outlet for bottled-up impulses. Rather, “in laboratory studies measuring short-term effects, exposure to violent pornography increases punitive behavior toward women.”

DO VIOLENT VIDEO GAMES TEACH SOCIAL SCRIPTS FOR VIOLENCE?

Experiments worldwide indicate that playing positive games produces positive effects (Greitemeyer & Mügge, 2014; Prot et al., 2014). For example, playing *Lemmings*, where a goal is to help others, increases real-life helping. So, might a parallel effect occur after playing games that enact violence? Violent video games became an issue for public debate after teenagers in more than a dozen places seemed to mimic the carnage in the shooter games they had so often played (Anderson, C. A., 2004, 2013).

In 2002, three young men in Michigan spent part of a night drinking beer and playing *Grand Theft Auto III*. Using simulated cars, they ran down pedestrians, then beat them with fists, leaving a bloody body behind (Kolker, 2002). These same young men then went out for a real drive. Spotting a 38-year-old man on a bicycle, they ran him down with their car, got out, stomped and punched him, and returned home to play the game some more. (The victim, a father of three, died six days later.)

This is but one anecdote, and, as we say in psychological science, “the plural of anecdote is not evidence.” Yet such incidents of violent mimicry make us wonder: What *are* the effects of actively role-playing aggression? Does it cause young people to become less sensitive to violence and more open to violent acts? Nearly 400 studies of 130,000 people offer some answers, report some researchers (Anderson et al., 2010): Video games can prime aggressive thoughts, decrease empathy, and increase aggression. University men who spend the most hours playing violent video games have also tended to be the most physically aggressive (Anderson & Dill, 2000). (For example, they more often acknowledged having hit or attacked someone else.) And people randomly assigned to play a game involving bloody murders with groaning victims (rather than to play nonviolent *Myst*) became more hostile. On a follow-up task, they were more likely to blast intense noise at a fellow student. Studies of young adolescents reveal that those who play a lot of violent video games become more aggressive and see the world as more hostile (Bushman, 2016; Exelmans et al., 2015; Gentile, 2009). Compared with nongaming kids, they get into more arguments and fights and

earn poorer grades.

AFP/Getty Images

Coincidence or cause?

In 2011, Norwegian Anders Behring Breivik bombed government buildings in Oslo, and then went to a youth camp where he shot and killed 69 people, mostly teens. As a player of first-person shooter games, Breivik stirred debate when he commented that “I see MW2 [*Modern Warfare 2*] more as a part of my training-simulation than anything else.” Did his violent game playing—and that of the 2012 mass murderer of Newtown, Connecticut’s first-grade children—contribute to the violence, or was it a merely coincidental association? To explore such questions, psychologists experiment.

Ah, but is this merely because naturally hostile kids are drawn to such games? Apparently not. Comparisons of gamers and nongamers who scored low on hostility measures revealed a difference in the number of fights they reported. Almost 4 in 10 violent-game players had been in fights, compared with only 4 in 100 of the nongaming kids (Anderson, C. A., 2004). Some researchers believe that, due partly to the more active participation and rewarded violence of game play, violent video games have even greater effects on aggressive behavior and cognition than do violent TV shows and movies (Anderson & Warburton, 2012).

“Research demonstrates a consistent relation between violent video game use and increases in aggressive behavior, aggressive cognitions

and aggressive affect, and decreases in prosocial behavior, empathy and sensitivity to aggression.”

American Psychological Association Task Force on Violent Media, 2015

Other researchers are unimpressed by such findings (Ferguson, 2013b, 2014, 2015). They note that from 1996 to 2006, video game sales increased yet youth violence declined. They argue that other factors—depression, family violence, peer influence—better predict aggression. The focused fun of game playing can also satisfy basic needs for a sense of competence, control, and social connection (Granic et al., 2014).

* * *

To sum up, research reveals biological, psychological, and social-cultural influences on aggressive behavior. Complex behaviors, including violence, have many causes, making any single explanation an oversimplification. Asking what causes violence is therefore like asking what causes cancer. Those who study the effects of asbestos exposure on cancer rates may remind us that asbestos is indeed a cancer cause, but it is only one among many. Like so much else, aggression is a biopsychosocial phenomenon ([FIGURE 13.10](#)).

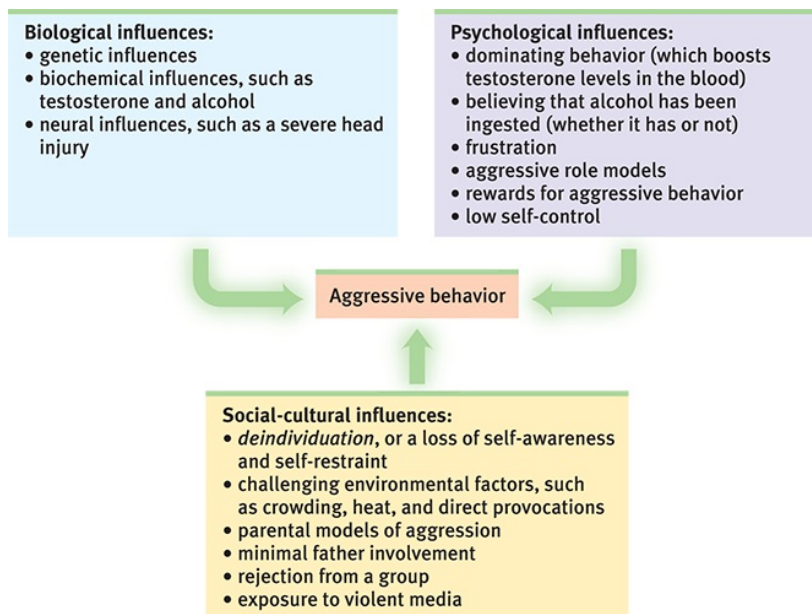

FIGURE 13.10 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 13.10 Biopsychosocial understanding of aggression

Because many factors contribute to aggressive behavior, there are many ways to change such behavior, including learning anger management and communication skills, and avoiding violent media and video games.

A happy concluding note: Historical trends suggest that the world is becoming less violent over time (Pinker, 2011). That people vary across time and place reminds us that environments differ. Yesterday's plundering Vikings have become today's peace-promoting Scandinavians. Like all behavior, aggression arises from the interaction of persons and situations.

RETRIEVAL PRACTICE

RP-13 What biological, psychological, and social-cultural influences interact to produce aggressive behaviors?

ANSWER: Our biology (our genes, neural systems, and biochemistry—including testosterone and alcohol levels) influences our aggressive tendencies. Psychological factors (such as frustration, previous rewards for aggressive acts, and observation of others' aggression) can trigger any aggressive tendencies we may have. Social influences, such as exposure to violent media or being ostracized from a group, and cultural influences, such as whether we've grown up in a "culture of honor" or a father-absent home, can also affect our aggressive responses.

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively

thanks to the *testing effect*.

Prejudice toward a group involves negative feelings, a tendency to discriminate, and overly generalized beliefs referred to as

_____.

If several well-publicized murders are committed by members of a particular group, we may tend to react with fear and suspicion toward all members of that group. What psychological principle can help explain this reaction?

The other-race effect occurs when we assume that other groups are _____ (more/less) homogeneous than our own group.

Evidence of a biochemical influence on aggression is the finding that

- a. aggressive behavior varies widely from culture to culture.
- b. animals can be bred for aggressiveness.
- c. stimulation of an area of the brain's limbic system produces aggressive behavior.
- d. a higher-than-average level of the hormone testosterone is associated with violent behavior in males.

Studies show that parents of delinquent young people tend to use beatings to enforce discipline. This suggests that aggression can be

- a. learned through direct rewards.
- b. triggered by exposure to violent media.
- c. learned through observation of aggressive models.
- d. caused by hormone changes at puberty.

A conference of social scientists studying the effects of pornography unanimously agreed that violent pornography

- a. has little effect on most viewers.
- b. is the primary cause of reported and unreported rapes.
- c. leads viewers to be more accepting of coercion in sexual relations.
- d. has no effect, other than short-term arousal and entertainment.

The aspect of pornographic films that most directly influences men's aggression toward women seems to be the

- a. length of the film.
- b. eroticism portrayed.
- c. depictions of sexual violence.
- d. attractiveness of the actors.

Answers are a click away in the e-book, and available in [Appendix D](#), at the back of the printed text.

Prosocial Relations

As social animals—as people who need people—we often approach people not with closed fists, but with open arms. Social psychologists focus not only on the dark side of social relationships, but also on the bright side, by studying *prosocial* behavior—behavior that intends to help or benefit someone. Our positive behaviors toward others are evident from explorations of attraction, altruism, and peacemaking.

Attraction

Pause a moment and think about your relationships with two people—a close friend, and someone who has stirred your romantic feelings. What psychological chemistry binds us together in friendship or love? Social psychology suggests some answers.

The Psychology of Attraction

LOQ 13-15 Why do we befriend or fall in love with some people but not others?

We endlessly wonder how we can win others' affection and what makes our own affections flourish or fade. Does familiarity breed contempt, or does it amplify affection? Do birds of a feather flock together, or do opposites attract? Is it what's inside that counts, or does physical attractiveness matter too? To explore these questions, let's consider three ingredients of our liking for one another: proximity, attractiveness, and similarity.

PROXIMITY Before friendships become close, they must begin. *Proximity*—geographic nearness—is friendship's most powerful predictor. Proximity can provide opportunities for aggression. But much more often it breeds liking (and sometimes even marriage) among those who live in the same neighborhood, sit nearby in class, work in the same office, share the same parking lot, or eat in the same dining hall. Look around. Mating starts with

meeting.

Brendan Beirne/REX/Shutterstock

Familiarity breeds acceptance

When this rare white penguin was born in the Sydney, Australia zoo, his tuxedoed peers ostracized him. Zookeepers thought they would need to dye him black to gain acceptance. But after three weeks of contact, the other penguins came to accept him.

Proximity breeds liking partly because of the [mere exposure effect](#). Repeated exposure to novel stimuli increases our liking for them. By age 3 months, infants prefer photos of the race they most often see—usually their own race (Kelly et al., 2007). For our ancestors, this mere exposure effect likely had survival value. What was familiar was generally safe and approachable. What was unfamiliar was more often dangerous and threatening. Evolution may therefore have hard-wired into us the tendency to bond with those who are familiar and to be wary of those whose looks are unfamiliar (Sofer et al., 2015; Zajonc, 1998).

mere exposure effect the phenomenon that repeated exposure to novel stimuli increases liking of them.

Mere exposure increases our liking not only for familiar faces, but also for nonsense syllables, musical selections, geometric figures, Chinese characters,

and the letters of our own name (Moreland & Zajonc, 1982; Nuttin, 1987; Zajonc, 2001). So, within certain limits, familiarity feeds fondness (Bornstein, 1989, 1999). This would come as no surprise to the young Taiwanese man who wrote more than 700 letters to his girlfriend, urging her to marry him. She did marry—the mail carrier (Steinberg, 1993).

Jeffrey Mayer/Getty Images

Which is the real Sofía Vergara?

The mere exposure effect applies even to ourselves. Because the human face is not perfectly symmetrical, the face we see in the mirror is not the same face our friends see. Most of us prefer the familiar mirror image, while our friends like the reverse (Mita et al., 1977). The person actress Sofía Vergara sees in the mirror each morning is shown at right, and that's the photo she would probably prefer.

No face is more familiar than your own. And that helps explain an interesting finding by Lisa DeBruine (2002, 2004): We like other people when their faces incorporate some morphed features of our own. When McMaster University students played a game with a supposed other player, they were more trusting and cooperative when the other person's image had some of their own facial features morphed into it. In me I trust.

MODERN MATCHMAKING Those who have not found a romantic partner in their immediate proximity may cast a wider net by joining an online dating service. Millions search for love on one of the 8000 online dating services (Hatfield, 2016). In 2015, 27 percent of 18- to 24-year-old Americans tried an online dating service or mobile dating app (Smith, 2016).

Online matchmaking definitely expands the pool of potential mates (Finkel et al., 2012a,b). But how effective is the matchmaking? Compared with those formed in person, Internet-formed friendships and romantic relationships are, on average, slightly more likely to last and be satisfying (Bargh & McKenna, 2004; Bargh et al., 2002; Cacioppo et al., 2013;

McKenna et al., 2002). In one study, people disclosed more, with less posturing, to those whom they met online (McKenna et al., 2002). When conversing online with someone for 20 minutes, they felt more liking for that person than they did for someone they had met and talked with face to face. This was true even when (unknown to them) it was the same person! Internet friendships often feel as real and important as in-person relationships.

© Dave Coverly/speedbump.com

Small wonder that one survey found a leading online matchmaker enabling more than 500 U.S. marriages a day (Harris Interactive, 2010). By one estimate, online dating now is responsible for about a fifth of U.S. marriages (Crosier et al., 2012). And in a national survey of straight and gay/lesbian couples, nearly a quarter of heterosexual couples and some two-thirds of same-sex couples met online (Rosenfeld & Thomas, 2012; see [FIGURE 13.11](#)).

FIGURE 13.11 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Rosenfeld & Thomas, 2012

FIGURE 13.11 Percentage of heterosexual and same-sex couples who met online

Speed dating pushes the search for romance into high gear. In a process pioneered by a matchmaking Jewish rabbi, people meet a succession of prospective partners, either in person or via webcam (Bower, 2009). After a 3- to 8-minute conversation, people move on to the next prospect. (In an in-person heterosexual meeting, one group—usually the women—remains seated while the other group circulates.) Those who want to meet again can arrange for future contact. For many participants, 4 minutes is enough time to form a feeling about a conversational partner and to register whether the partner likes them (Eastwick & Finkel, 2008a,b).

"I'd like to meet the algorithm that thought we'd be a good match."

William Haefeli The New Yorker Collection/
The Cartoon Bank

For researchers, speed dating offers a unique opportunity for studying influences on our first impressions of potential romantic partners. Some recent findings:

- *People who fear rejection often elicit rejection.* After a 3-minute speed date, those who most feared rejection were least often selected for a follow-up date (McClure & Lydon, 2014).
- *Given more options, people make more superficial choices.* When people meet lots of potential partners, they focus on more easily assessed characteristics, such as height and weight (Lenton & Francesconi, 2010).
- *Men wish for future contact with more of their speed dates; women tend to be choosier.* But this difference disappears if the conventional roles are reversed, so that men stay seated while women circulate (Finkel & Eastwick, 2009).

PHYSICAL ATTRACTIVENESS Once proximity affords us contact, what most affects our first impressions? The person's sincerity? Intelligence? Personality? Hundreds of experiments reveal that it is something more superficial: physical appearance. This finding is unnerving for those of us taught that "beauty is only skin deep" and "appearances can be deceiving."

In one early study, researchers randomly matched new University of

Minnesota students for a Welcome Week dance (Walster et al., 1966). Before the dance, the researchers gave each student a battery of personality and aptitude tests, and they rated each student's physical attractiveness. During the blind date, the couples danced and talked for more than two hours and then took a brief intermission to rate their dates. What predicted whether they liked each other? Only one thing: appearance. Both the men and the women liked good-looking dates best. Women are more likely than men to say that another's looks don't affect them (Lippa, 2007). But studies show that a man's looks do affect women's behavior (Eastwick et al., 2014a,b). In speed-dating experiments, as in Tinder swipes, attractiveness influences first impressions for both sexes (Belot & Francesconi, 2006; Finkel & Eastwick, 2008).

Physical attractiveness also predicts how often people date and how popular they feel. And it affects initial impressions of people's personalities. We don't assume that attractive people are more compassionate, but we do perceive them as healthier, happier, more sensitive, more successful, and more socially skilled (Eagly et al., 1991; Feingold, 1992; Hatfield & Sprecher, 1986).

For those of us who find the importance of looks unfair and unenlightened, three other findings may be reassuring.

“Personal beauty is a greater recommendation than any letter of introduction.”

Aristotle, *Apothegems*, 330 B.C.E.

- People's attractiveness is surprisingly unrelated to their self-esteem and happiness (Diener et al., 1995; Major et al., 1984). Unless we have just compared ourselves with superattractive people, few of us (thanks, perhaps, to the mere exposure effect) view ourselves as unattractive (Thornton & Moore, 1993).
- Strikingly attractive people are sometimes suspicious that praise for their work may simply be a reaction to their looks. Less attractive people have been more likely to accept praise as sincere (Berscheid, 1981).
- For couples who were friends before lovers—who became romantically involved long after first meeting—looks matter less (Hunt et al., 2015).

With slow-cooked love, shared values and interests matter more.

Beauty is also in the eye of the culture. Hoping to look attractive, people across the globe have pierced and tattooed their bodies, lengthened their necks, bound their feet, and artificially lightened or darkened their skin and hair. They have gorged themselves to achieve a full figure or liposuctioned fat to achieve a slim one, applied chemicals to rid themselves of unwanted hair or to regrow wanted hair, strapped on leather garments to make their breasts seem smaller or relied on push-up bras and surgery to make them look bigger. Cultural ideals change over time. For women in North America, the ultra-thin ideal of the Roaring Twenties gave way to the soft, voluptuous Marilyn Monroe ideal of the 1950s, only to be replaced by today's lean yet busty ideal.

Percentage of Men and Women Who “Constantly Think About Their Looks”

	Men	Women
Canada	18%	20%
United States	17	27
Mexico	40	45
Venezuela	47	65

From Roper Starch survey, reported by McCool (1999).

Some aspects of heterosexual attractiveness, however, do cross place and time (Cunningham et al., 2005; Langlois et al., 2000). By providing reproductive clues, bodies influence sexual attraction. As evolutionary psychologists explain, men in many cultures, from Australia to Zambia, judge women as more attractive if they have a youthful, fertile appearance, suggested by a low waist-to-hip ratio (Karremans et al., 2010; Perilloux et al., 2010; Platek & Singh, 2010). Women feel attracted to healthy-looking men, but especially—and more so when ovulating—to those who seem mature, dominant, masculine, and affluent (Gallup & Frederick, 2010; Gangestad et

al., 2010).

Women have 91 percent of cosmetic procedures (ASPS, 2010). Women also recall others' appearances better than do men (Mast & Hall, 2006).

Estimated length of human nose removed by U.S. plastic surgeons each year: 5469 feet (*Harper's*, 2009).

Sean Caffrey/Getty Images; Blend Images/Alamy; svetikd/Getty Images

In the eye of the beholder

Conceptions of attractiveness vary by culture and over time. Yet some adult physical features, such as a healthy appearance and a relatively symmetrical face, seem attractive everywhere.

Faces matter, too. When people rate opposite-sex faces and bodies separately, the face tends to be the better predictor of overall physical attractiveness (Currie & Little, 2009; Peters et al., 2007). So what makes a face attractive? Part of the answer is features that are neither unusually large nor small. Symmetrical faces and bodies are also perceived as more sexually attractive (Rhodes et al., 1999; Singh, 1995; Thornhill & Gangestad, 1994). This helps explain why an averaged (and therefore symmetrical) face is attractive (**FIGURE 13.12**). In one clever demonstration, researchers digitized the faces of up to 32 college students and used a computer to average them (Langlois & Roggman, 1990). The result? Viewers judged the averaged, composite faces as more attractive than 96 percent of the individual faces. (If only we could merge either half of our face with its mirror image: Our symmetrical new face would be a notch more attractive.)

FIGURE 13.12 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
David Perrett/University of St. Andrews

FIGURE 13.12 Average is attractive

Which of these faces offered by University of St. Andrews psychologist David Perrett (2002, 2010) is most attractive? Most people say it's the face on the right—of a nonexistent person that is the average composite of these 3 plus 57 other actual faces.

Our feelings also influence our attractiveness judgments. Imagine two people: One is honest, humorous, and polite. The other is rude, unfair, and abusive. Which one is more attractive? Most people perceive the person with the appealing traits as more physically attractive (Lewandowski et al., 2007). Or imagine being paired with a stranger of the sex you find attractive—someone who listens intently to your self-disclosures. Might you feel a twinge of sexual attraction toward that empathic person? Student volunteers did, in several experiments (Birnbau & Reis, 2012). Our feelings influence our perceptions. Those we like we find attractive.

In a Rodgers and Hammerstein musical, Prince Charming asks Cinderella, “Do I love you because you’re beautiful, or are you beautiful because I love you?” Chances are it’s both. As we see our loved ones again and again, their physical imperfections grow less noticeable and their attractiveness grows more apparent (Beaman & Klentz, 1983; Gross & Crofton, 1977). Shakespeare said it in *A Midsummer Night’s Dream*: “Love looks not with the eyes, but with the mind.” Come to love someone and watch beauty grow. Love sees loveliness.

"Play coy if you like, but no one can resist a perfectly symmetrical face."

Zachary Kanin The New Yorker Collection/
The Cartoon Bank

John Shearer/Getty Images; Bennett Raglin/Getty Images

Extreme makeover

In affluent, beauty-conscious cultures, increasing numbers of people, such as reality TV star Kylie Jenner, have turned to cosmetic procedures to change their looks.

SIMILARITY So proximity has brought you into contact with someone, and your appearance has made an acceptable first impression. What influences whether you will become friends? As you get to know each other, will the chemistry be better if you are opposites or if you are alike?

It makes a good story—extremely different types liking or loving each other: Rat, Mole, and Badger in *The Wind in the Willows*, Frog and Toad in Arnold Lobel's books, Edward and Bella in the *Twilight* series. The stories delight us by expressing what we seldom experience. In real life, opposites retract (Rosenbaum, 1986; Montoya & Horton, 2013). Compared with

randomly paired people, friends and couples are far more likely to share common attitudes, beliefs, and interests (and, for that matter, age, religion, race, education, intelligence, smoking behavior, and economic status). Moreover, the more alike people are, the more their liking endures (Byrne, 1971; Hartl et al., 2015). Journalist Walter Lippmann was right to suppose that love lasts “when the lovers love many things together, and not merely each other.” Similarity breeds content.

Proximity, attractiveness, and similarity are not the only determinants of attraction. We also like those who like us. This is especially true when our self-image is low. When we believe someone likes us, we feel good and respond to them warmly, which leads them to like us even more (Curtis & Miller, 1986). To be liked is powerfully rewarding.

Indeed, all the findings we have considered so far can be explained by a simple *reward theory of attraction*: We will like those whose behavior is rewarding to us, including those who are both able and willing to help us achieve our goals (Montoya & Horton, 2014). When people live or work in close proximity to us, it requires less time and effort to develop the friendship and enjoy its benefits. When people are attractive, they are aesthetically pleasing, and associating with them can be socially rewarding. When people share our views, they reward us by validating our beliefs.

Similarity attracts; perceived dissimilarity does not.

RETRIEVAL PRACTICE

RP-14 People tend to marry someone who lives or works nearby. This is an example of the _____ in action.

ANSWER: mere exposure effect.

RP-15 How does being physically attractive influence others’ perceptions?

ANSWER: Being physically attractive tends to elicit positive first impressions. People tend to assume that attractive people are healthier, happier, and more socially skilled than others are.

Romantic Love

LOQ 13-16 How does romantic love typically change as time passes?

Sometimes people move quickly from initial impressions, to friendship, to the more intense, complex, and mysterious state of romantic love. If love endures, temporary *passionate love* will mellow into a lingering *companionate love* (Hatfield, 1988).

PASSIONATE LOVE [Passionate love](#) mixes something new with something positive (Aron et al., 2000; Coulter & Malouff, 2013). We intensely desire to be with our partner (Hatfield et al., 2015). Seeing our partner stimulates blood flow to a brain region linked to craving and obsession (Acevedo et al., 2012).

passionate love an aroused state of intense positive absorption in another, usually present at the beginning of a romantic relationship.

The two-factor theory of emotion ([Chapter 12](#)) explains the intense positive absorption of romantic love (Hatfield, 1988). That theory assumes that

Bill looked at Susan, Susan at Bill. Suddenly death didn't seem like an option. This was love at first sight.

© Jason Love

- emotions have two ingredients—*physical arousal* plus *cognitive appraisal*.
- arousal from any source can enhance one emotion or another, depending on how we interpret and label the arousal.

In tests of the two-factor theory, college men have been aroused by fright, by running in place, by viewing erotic materials, or by listening to humorous or repulsive monologues. They were then introduced to an attractive woman and asked to rate her (or their girlfriend). Unlike unaroused men, the stirred-up men attributed some of their arousal to the woman or girlfriend, and felt more attracted to her (Carducci et al., 1978; Dermer & Pyszczynski, 1978; White & Kight, 1984). In one classic experiment, researchers studied people

crossing two bridges above British Columbia's rocky Capilano River (Dutton & Aron, 1974, 1989). One, a swaying footbridge, was 230 feet above the rocks; the other was low and solid. As men came off each bridge, an attractive young woman (working for the researchers) intercepted them and asked them to fill out a short questionnaire. She then offered her phone number in case they wanted to hear more about her project. Far more of the men who had just crossed the high bridge—which left their hearts pounding—accepted the number and later called the woman.

To be revved up and to associate some of that arousal with a desirable person is to feel the pull of passion. Adrenaline makes the heart grow fonder. Sexual desire + a growing attachment = passionate love (Berscheid, 2010).

COMPANIONATE LOVE Although the desire and attachment of romantic love often endure, the intense absorption in the other, the thrill of the romance, the giddy “floating on a cloud” feelings typically fade. Does this mean the French are correct in saying that “love makes the time pass and time makes love pass”? Or can friendship and commitment keep a relationship going after the passion cools?

As love matures, it typically becomes a steadier [companionate love](#)—a deep, affectionate attachment (Hatfield, 1988). Like a passing storm, the flood of passion-facilitating hormones (testosterone, dopamine, adrenaline) subsides. But another hormone, *oxytocin*, remains, supporting feelings of trust, calmness, and bonding with the mate. This shift from passion to attachment may have adaptive value (Reis & Aron, 2008). Passionate love often produces children, whose survival is aided by the parents' waning obsession with each other.

companionate love the deep affectionate attachment we feel for those with whom our lives are intertwined.

In the most satisfying marriages, attraction and sexual desire endure, minus the obsession of early stage romance (Acevedo & Aron, 2009). Indeed, failure to appreciate passionate love's limited half-life can doom a relationship (Berscheid et al., 1984). Recognizing the short duration of obsessive passionate love, some societies deem such feelings an irrational

reason for marrying. Better, they say, to search for (or have someone choose for you) a partner with a compatible background and interests. Non-Western cultures, where people rate love as less important for marriage, do have lower divorce rates (Levine et al., 1995).

“When two people are under the influence of the most violent, most insane, most delusive, and most transient of passions, they are required to swear that they will remain in that excited, abnormal, and exhausting condition continuously until death do them part.”

George Bernard Shaw, “Getting Married,” 1908

One key to a gratifying and enduring relationship is [equity](#). When equity exists—when both partners receive in proportion to what they give—their chances for sustained and satisfying companionate love have been good (Gray-Little & Burks, 1983; Van Yperen & Buunk, 1990). In one national survey, “sharing household chores” ranked third, after “faithfulness” and a “happy sexual relationship,” on a list of nine things people associated with successful marriages. As the Pew Research Center (2007) summarized, “I like hugs. I like kisses. But what I really love is help with the dishes.”

equity a condition in which people receive from a relationship in proportion to what they give to it.

Equity’s importance extends beyond marriage. Mutually sharing one’s self and possessions, making decisions together, giving and getting emotional support, promoting and caring about each other’s welfare—all of these acts are at the core of every type of loving relationship (Sternberg & Grajek, 1984). It’s true for lovers, for parent and child, and for close friends.

Sharing includes [self-disclosure](#), revealing intimate details about ourselves—our likes and dislikes, our dreams and worries, our proud and shameful moments. “When I am with my friend,” noted the Roman statesman Seneca, “me thinks I am alone, and as much at liberty to speak anything as to think it.” Self-disclosure breeds liking, and liking breeds self-disclosure (Collins & Miller, 1994). As one person reveals a little, the other

reciprocates, the first then reveals more, and on and on, as friends or lovers move to deeper levels of intimacy (Baumeister & Bratslavsky, 1999).

self-disclosure the act of revealing intimate aspects of oneself to others.

2430/Getty Images

Love is an ancient thing

In 2007, a 5000- to 6000-year-old “Romeo and Juliet” young couple was unearthed locked in embrace, near Rome.

One experiment marched some student pairs through 45 minutes of increasingly self-disclosing conversation—from “What is the greatest accomplishment of your life?” to “When did you last cry in front of another person? By yourself?” Other pairs spent the time with small-talk questions, such as “What was your high school like?” (Aron et al., 1997). By the experiment’s end, those experiencing the escalating intimacy felt much closer to their conversation partner than did the small-talkers. Likewise, after dating couples spent 45 minutes answering such questions, they felt increased love (Welker et al., 2014).

HI & LOIS

HI & LOIS © 1992 by King Features Syndicate, Inc. World Rights Reserved.

In addition to equity and self-disclosure, a third key to enduring love is *positive support*. Relationship conflicts are inevitable, but hurtful communications are not. Do we more often express sarcasm or support, scorn or sympathy, sneers or smiles? For unhappy couples, disagreements, criticisms, and put downs are routine. For happy couples in enduring relationships, positive interactions (compliments, touches, laughing) outnumber negative interactions (sarcasm, disapproval, insults) by at least 5 to 1 (Gottman, 2007; see also Sullivan et al., 2010).

In the mathematics of love, self-disclosing intimacy + mutually supportive equity = enduring companionate love.

RETRIEVAL PRACTICE

RP-16 How does the two-factor theory of emotion help explain *passionate love*?

ANSWER: Emotions consist of (1) physical arousal and (2) our interpretation of that arousal. Researchers have found that any source of arousal (running, fear, laughter) may be interpreted as passion in the presence of a desirable person.

RP-17 Two vital components for maintaining companionate love are _____ and _____.

ANSWER: equity; self-disclosure

Altruism

LOQ 13-17 What is *altruism*? When are people most—and least—likely to help?

Altruism is an unselfish concern for the welfare of others. In rescuing his jailer, Dirk Willems exemplified altruism. Willems fits the definition of a *hero*—moral, courageous, and protective of those in need (Kinsella et al., 2015). Carl Wilkens and Paul Rusesabagina displayed another heroic example of altruism in Kigali, Rwanda. Wilkens, a Seventh-day Adventist missionary, was living there in 1994 with his family when militia from the Hutu ethnic group began to slaughter members of a minority ethnic group, the Tutsis. The U.S. government, church leaders, and friends all implored Wilkens to leave. He refused. After evacuating his family, and after every other American had left Kigali, he alone stayed and contested the 800,000-person genocide. When the militia came to kill him and his Tutsi servants, Wilkens' Hutu neighbors deterred them. Despite repeated death threats, he spent his days running roadblocks to take food and water to orphanages and to negotiate, plead, and bully his way through the bloodshed, saving lives time and again. “It just seemed the right thing to do,” he later explained (Kristof, 2004).

altruism unselfish regard for the welfare of others.

FINBARR O'REILLY/REUTERS/Newscom

Why do genocides occur?

An estimated 800,000 people died during the Rwandan Genocide of 1994, when Hutu groups carried out mass killings of Tutsis. Social psychology research helps us understand some of the factors motivating genocides. We tend to categorize our world into us and them, and, when threatened, to feel greater animosity toward outside groups.

Elsewhere in Kigali, Rusesabagina, a Hutu married to a Tutsi and the acting manager of a luxury hotel, was sheltering more than 1200 terrified Tutsis and moderate Hutus. When international peacekeepers abandoned the city and hostile militia threatened his guests in the “Hotel Rwanda” (as it came to be called in a 2004 movie), the courageous Rusesabagina began cashing in past favors. He bribed the militia and telephoned influential people abroad to exert pressure on local authorities, thereby sparing the lives of the hotel’s occupants, despite the surrounding chaos. Both Wilkens and Rusesabagina were displaying altruism, an unselfish regard for the welfare of others.

Altruism became a major concern of social psychologists after an especially vile act. On March 13, 1964, a stalker repeatedly stabbed Kitty Genovese, then raped her as she lay dying outside her Queens, New York, apartment at 3:30 a.m. “Oh, my God, he stabbed me!” Genovese screamed into the early morning stillness. “Please help me!” Windows opened and lights went on as some neighbors heard her screams. Her attacker fled and then returned to stab and rape her again. Until it was too late, no one called police or came to her aid.

Bystander Intervention

Although initial reports of the Genovese murder overestimated the number of witnesses, the reports triggered outrage over the bystanders’ apparent “apathy” and “indifference.” Rather than blaming the onlookers, social psychologists John Darley and Bibb Latané (1968b) attributed their inaction to an important situational factor—the presence of others. Given certain circumstances, they suspected, most of us might behave similarly. To paraphrase the French writer Voltaire, we all are guilty of the good we did not do.

After staging emergencies under various conditions, Darley and Latané

assembled their findings into a decision scheme: We will help only if the situation enables us first to *notice* the incident, then to *interpret* it as an emergency, and finally to *assume responsibility* for helping (**FIGURE 13.13**). At each step, the presence of others can turn us away from the path that leads to helping.

FIGURE 13.13 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Viviane Moos/Getty Images

FIGURE 13.13 The decision-making process for bystander intervention

Before helping, one must first notice an emergency, then correctly interpret it, and then feel responsible. (Adapted from Darley & Latané, 1968b.)

“Probably no single incident has caused social psychologists to pay as much attention to an aspect of social behavior as Kitty Genovese’s murder.”

R. Lance Shotland (1984)

One of Darley and Latané’s experiments staged a fake emergency as students in separate laboratory rooms took turns talking over an intercom. Only the person whose microphone was switched on could be heard. When his turn came, one student (an accomplice of the experimenters) pretended to have an epileptic seizure, and he called for help (Darley & Latané, 1968a).

How did the others react? As **FIGURE 13.14** shows, those who believed only they could hear the victim—and therefore thought they alone were responsible for helping him—usually went to his aid. Students who thought others could also hear the victim’s cries were more likely to do nothing. When more people shared responsibility for helping—when there was a *diffusion of responsibility*—any single listener was less likely to help. Inattention and diffused responsibility also contribute to the “global bystander nonintervention” as millions of far-away people die of hunger, disease, and genocide (Pittinsky & Diamante, 2015).

Data from Darley & Latané, 1968a.

FIGURE 13.14 Responses to a simulated emergency

When people thought they alone heard the calls for help from a person they believed to be having an epileptic seizure, they usually helped. But when they thought four others were also hearing the calls, fewer than one-third responded.

For a review of research on emergency helping, engage online with
Concept Practice: When Will People Help Others?

Hundreds of additional experiments have confirmed this [bystander effect](#). For example, researchers and their assistants took 1497 elevator rides in three cities and “accidentally” dropped coins or pencils in front of 4813 fellow passengers (Latané & Darley, 1968). When alone with the person in need, 40 percent helped; in the presence of 5 other bystanders, only 20 percent helped. The presence of bystanders reduces brain activation in the motor cortex, signaling that we don’t need to take action (Houtenhuys & de Gelder, 2014).

bystander effect the tendency for any given bystander to be less likely to give aid if other bystanders are present.

Observations of behavior in thousands of these situations—relaying an emergency phone call, aiding a stranded motorist, donating blood, picking up

dropped books, contributing money, giving time—show that the odds of our helping someone depend on the characteristics of the person, the situation, and our own internal state. The odds of helping are highest when

- the person appears to need and deserve help.
- the person is in some way similar to us.
- the person is a woman.
- we have just observed someone else being helpful.
- we are not in a hurry.
- we are in a small town or rural area.
- we are feeling guilty.
- we are focused on others and not preoccupied.
- we are in a good mood.

This last result, that happy people are helpful people, is one of psychology's most consistent findings. As poet Robert Browning (1868) observed, "Oh, make us happy and you make us good!" It doesn't matter how we are cheered. Whether by being made to feel successful and intelligent, by thinking happy thoughts, by finding money, or even by receiving a posthypnotic suggestion, we become more generous and more eager to help (Carlson et al., 1988). And if our feeling of elevation follows witnessing or learning of someone else's self-giving deed, our helping will become even more pronounced (Schnall et al., 2010).

So happiness breeds helpfulness. But it's also true that helpfulness breeds happiness. Helping those in need activates brain areas associated with reward (Harbaugh et al., 2007; Kawamichi et al., 2015). That helps explain a curious finding: People who give money away are happier than those who spend it almost entirely on themselves. In one controlled experiment, researchers gave people an envelope with cash and instructed one group to spend it on themselves and another to spend it on others (Dunn et al., 2008; Dunn & Norton, 2013). Which group was happiest at the day's end? It was, indeed, those assigned to the spend-it-on-others condition. And in a survey of more than 200,000 people worldwide, people in both rich and poor countries were happier with their lives if they had donated to a charity in the last month. Just reflecting on an instance of spending money on others provides most people with a mood boost (Aknin et al., 2013).

RETRIEVAL PRACTICE

RP-18 Why didn't anybody help Kitty Genovese? What social psychology principle did this incident illustrate?

ANSWER: In the presence of others, an individual is less likely to notice a situation, correctly interpret it as an emergency, and take responsibility for offering help. The Kitty Genovese case demonstrated this *bystander effect*, as each witness assumed many others were also aware of the event.

Helping—Self-Interest or Socialization?

LOQ 13-18 How do social exchange theory and social norms explain helping behavior?

Why do we help? One widely held view is that self-interest underlies all human interactions, that our constant goal is to maximize rewards and minimize costs. Accountants call it *cost-benefit analysis*. Philosophers call it *utilitarianism*. Social psychologists call it [social exchange theory](#). If you are considering donating blood, you may weigh the costs of doing so (time, discomfort, anxiety) against the benefits (reduced guilt, social approval, good feelings). If the rewards exceed the costs, you will help.

social exchange theory the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs.

Others believe we help because we have been socialized to do so, through norms that prescribe how we *ought* to behave (Everett et al., 2015). Two such norms are the *reciprocity norm* and the *social-responsibility norm*:

The **reciprocity norm** is the expectation that we should return help, not harm, to those who have helped us. In our relations with others of similar status, this norm compels us to give (in favors, gifts, or social invitations) about as much as we receive. Sometimes this means “paying it forward,” as happened in one experiment, when people who were treated generously became more likely to be generous to a stranger (Tsvetkova & Macy, 2014). Returning favors feels good, making the norm of reciprocity a pleasant strategy to help others (Hein et al., 2016).

reciprocity norm an expectation that people will help, not hurt, those who have helped them.

© 2014 Steve Kelley, reprinted with permission

The reciprocity norm kicked in after Dave Tally, a Tempe, Arizona, homeless man, found \$3300 in a backpack that an Arizona State University student had misplaced on his way to buy a used car (Lacey, 2010). Instead of using the cash for much-needed bike repairs, food, and shelter, Tally turned the backpack in to the social service agency where he volunteered. To

reciprocate Tally's help, the backpack's owner thanked him with a reward. Hearing about Tally's self-giving deeds, dozens of others also sent him money and job offers.

The **social-responsibility norm** is the expectation that we should help those who need our help—young children and others who cannot give as much as they receive—even if the costs outweigh the benefits. Europeans are most welcoming of asylum seekers who are most vulnerable—those, for example, who have been tortured or have no surviving family (Bansak et al., 2016). Construction worker Wesley Autrey exemplified the social-responsibility norm on January 2, 2007. He and his 6- and 4-year-old daughters were awaiting a New York City subway train when, before them, a man collapsed in a seizure, got up, then stumbled to the platform's edge and fell onto the tracks. With train headlights approaching, "I had to make a split-second decision," Autrey later recalled (Buckley, 2007). His decision, as his girls looked on in horror, was to leap from the platform, push the man off the tracks and into a foot-deep space between them, and lay atop him. As the train screeched to a halt, five cars traveled just above his head, leaving grease on his knit cap. When Autrey cried out, "I've got two daughters up there. Let them know their father is okay," onlookers erupted into applause.

social-responsibility norm an expectation that people will help those needing their help.

Nick Brooks/Newsday/AP Photo

Subway hero Wesley Autrey:

“I don’t feel like I did something spectacular; I just saw someone who needed help.” Five years later, a similar situation occurred when another man was shoved onto subway tracks—but this time, no one helped (Nocera, 2012). Social psychologists have wondered: Under what conditions will people help?

Many world religions encourage their followers to practice the social-responsibility norm, and sometimes this leads to prosocial behavior. Between 2006 and 2008, Gallup polls sampled more than 300,000 people across 140 countries, comparing the “highly religious” (who said religion was important to them and who had attended a religious service in the prior week) to those less religious. The highly religious, despite being poorer, were about 50 percent more likely to report having “donated money to a charity in the last month” and to have volunteered time to an organization (Pelham & Crabtree, 2008).

Conflict and Peacemaking

Positive social norms encourage generosity and enable group living. But conflicts often divide us. One response to recent mass migrations has been increasing nationalism and nativism. Moreover, *every day*, the world continues to spend almost \$5 billion for arms and armies—money that could be used for badly needed housing, nutrition, education, and health care. Knowing that wars begin in human minds, psychologists have wondered: What in the human mind causes destructive conflict? How might the perceived threats of social diversity be replaced by a spirit of cooperation?

Elements of Conflict

LOQ 13-19 How do social traps and mirror-image perceptions fuel social conflict?

To a social psychologist, a **conflict** is a perceived incompatibility of actions, goals, or ideas. The elements of conflict are much the same, whether partners sparring, political groups feuding, or nations at war. In each situation, conflict may seed positive change, or be a destructive process that can produce unwanted results. Among these processes are *social traps* and *distorted perceptions*.

conflict a perceived incompatibility of actions, goals, or ideas.

SOCIAL TRAPS In some situations, pursuing our personal interests also supports our collective well-being. As capitalist Adam Smith wrote in *The Wealth of Nations* (1776), “It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest.” In other situations, we *harm* our collective well-being by pursuing our personal interests. Such situations are **social traps**.

social trap a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior.

Researchers have created mini social traps in laboratory games that require two participants to choose between pursuing their immediate self-interest, at others' expense, versus cooperating for mutual benefits. Many real-life situations similarly pit our individual interests against our communal well-being. Individual fish trawlers reasoned that the fish they took would not threaten the species and that if they didn't take them, others would anyway. The result: Some fish stocks have been depleted. Ditto for the buffalo hunters of yesterday and the elephant-tusk poachers of today. Individual car owners and home owners reason, "Electric cars are more expensive. Besides, the fuel that I burn in my one car doesn't noticeably add to the greenhouse gases." When enough people reason similarly, the collective result threatens disaster—climate change, rising seas, and more extreme weather.

Social traps challenge us to reconcile our right to pursue our personal well-being with our responsibility for the well-being of all. Psychologists have therefore explored ways to convince people to cooperate for their mutual betterment—through agreed-upon *regulations*, through better *communication*, and through promoting *awareness* of our responsibilities toward community, nation, and the whole of humanity (Dawes, 1980; Linder, 1982; Sato, 1987). Given effective regulations, communication, and awareness, people more often cooperate, whether playing a laboratory game or the real game of life.

Jeff J Mitchell/Getty Images

Not in my ocean!

Many people support alternative energy sources, including wind turbines. But proposals to construct wind farms in real-world places elicit less support. Potential wind turbines in the Highlands and off the coast of Scotland produced heated debate over the benefits of clean energy versus the costs of altering treasured scenic views.

ENEMY PERCEPTIONS Psychologists have noted that those in conflict have a curious tendency to form diabolical images of one another. These distorted images are, ironically, so similar that we call them **mirror-image perceptions**: As we see “them”—as untrustworthy, with evil intentions—so “they” see us. Each demonizes the other. My political party has benevolent motives; the other party is malevolent (Waytz et al., 2014).

mirror-image perceptions mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive.

Mirror-image perceptions can often feed a vicious cycle of hostility. If

Juan believes Maria is annoyed with him, he may snub her, causing her to act in ways that justify his perception. As with individuals, so with countries. Perceptions can become **self-fulfilling prophecies**—beliefs that confirm themselves by influencing the other country to react in ways that seem to justify them.

self-fulfilling prophecy a belief that leads to its own fulfillment.

Individuals and nations alike tend to see their own actions as responses to provocation, not as the causes of what happens next. Perceiving themselves as returning tit for tat, they often hit back harder, as University College London volunteers did in one experiment (Shergill et al., 2003). Their task: After feeling pressure on their own finger, they were to use a mechanical device to press on another volunteer's finger. Although told to reciprocate with the same amount of pressure, they typically responded with about 40 percent more force than they had just experienced. Despite seeking only to respond in kind, their touches soon escalated to hard presses, much as when each child after a fight claims that "I just poked him, but he hit me harder."

Mirror-image perceptions feed similar cycles of hostility on the world stage. To most people, torture seems more justified when done by "us" rather than "them" (Tarrant et al., 2012). In American media reports, Muslims who kill have been portrayed as fanatical, hateful terrorists, while an American who allegedly killed 16 Afghans was portrayed as stressed out from marriage problems, four tours of duty, and a friend's having had his leg blown off (Greenwald, 2012).

The point is not that truth must lie midway between two such views (one may be more accurate). The point is that enemy perceptions often form mirror images. Moreover, as enemies change, so do perceptions. In American minds and media, the "bloodthirsty, cruel, treacherous" Japanese of World War II later became our "intelligent, hardworking, self-disciplined, resourceful allies" (Gallup, 1972).

RETRIEVAL PRACTICE

RP-19 Why do sports fans tend to feel a sense of satisfaction when

their archrival team loses? Do such feelings, in other settings, make conflict resolution more challenging?

ANSWER: Sports fans may feel they are part of an *ingroup* that sets itself apart from an *outgroup* (fans of the archrival team). Ingroup bias tends to develop, leading to prejudice and the view that the outgroup “deserves” misfortune. So, the archrival team’s loss may seem justified. In conflicts, this kind of thinking is problematic, especially when each side in the conflict develops *mirror-image perceptions* of the other (distorted, negative images that are ironically similar).

Promoting Peace

LOQ 13-20 What can we do to promote peace?

How can we make peace? Can contact, cooperation, communication, and conciliation transform the antagonisms fed by prejudice and conflicts into attitudes that promote peace? Research indicates that, in some cases, they can.

CONTACT Does it help to put two conflicting parties into close contact? It depends. Negative contact increases *disliking* (Graf et al., 2014; Paolini et al., 2014). But positive contact—especially noncompetitive contact between parties of equal status, such as fellow store clerks—typically helps. Initially prejudiced co-workers of different races have, in such circumstances, usually come to accept one another. This finding is confirmed by a statistical digest of more than 500 studies of face-to-face contact between majority people and outgroups (such as ethnic minorities, older people, and people with disabilities). Among the quarter-million people studied across 38 nations, contact has been correlated with, or in experimental studies has led to, more positive attitudes (Al Ramiah & Hewstone, 2013; Lemmer & Wagner, 2015; Pettigrew & Tropp, 2011). Some examples:

- With cross-racial contact, South Africans’ interracial attitudes have moved “into closer alignment” (Dixon et al., 2007; Finchilescu & Tredoux, 2010; Swart et al., 2011).

- Heterosexuals' attitudes toward gay people are influenced not only by *what* they know but also by *whom* they know (Collier et al., 2012; Smith et al., 2009). In surveys, the reason people most often give for becoming more supportive of same-sex marriage is "having friends, family, or acquaintances who are gay or lesbian" (Pew, 2013b). And in the United States, where attitudes toward gays have become more positive, 87 percent of people now say they know someone who is gay (Pew, 2016).
- Friendly contact, say between Blacks and Whites as roommates, improves attitudes toward others of the different race, and even toward other racial groups (Gaither & Sommers, 2013; Tausch et al., 2010).

However, contact is not always enough. In most desegregated schools, ethnic groups re-segregate themselves in lunchrooms, in classrooms, and elsewhere on school grounds (Alexander & Tredoux, 2010; Clack et al., 2005; Schofield, 1986). People in each group often think that they would welcome more contact with the other group, but they assume the other group does not reciprocate the wish (Richeson & Shelton, 2007). "I don't reach out to them, because I don't want to be rebuffed; they don't reach out to me, because they're just not interested." When such mirror-image misperceptions are corrected, friendships may form and prejudices melt.

COOPERATION To see if enemies could overcome their differences, researcher Muzafer Sherif (1966) set a conflict in motion. He separated 22 Oklahoma City boys into two separate camp areas. Then he had the two groups compete for prizes in a series of activities. Before long, each group became intensely proud of itself and hostile to the other group's "sneaky," "smart-alecky stinkers." Food wars broke out. Cabins were ransacked. Fistfights had to be broken up by camp counselors. Brought together, the two groups avoided each other, except to taunt and threaten. Little did they know that within a few days, they would be friends.

Sherif accomplished this by giving them superordinate goals—shared goals that could be achieved only through cooperation. When he arranged for the camp water supply to "fail," all 22 boys had to work together to restore the water. To rent a movie in those pre-Netflix days, they all had to pool their resources. To move a stalled truck, the boys needed to combine their strength, pulling and pushing together. Having used isolation and competition to make strangers into enemies, Sherif used shared predicaments and goals to turn

enemies into friends. What reduced conflict was not mere contact, but *cooperative* contact.

superordinate goals shared goals that override differences among people and require their cooperation.

A shared predicament likewise can have a powerfully unifying effect on other groups as well. Children and youth exposed to war, and minority group members facing rejection or discrimination, likewise develop strong ingroup identification (Bauer et al., 2014; Ramos et al., 2012). Israeli children growing up in conflict areas often develop a conflict-supportive narrative of perceptions, beliefs, and emotions regarding their shared adversary (Nasie et al., 2016). Such narratives build ingroup solidarity but also insensitivity to the pain experienced by outgroup members (Levy et al., 2016). In the aftermath of a divisive political primary election, party members will usually reunify when facing their shared threat—the opposition party candidate.

“Me against my brother, my brothers and me against my cousins, then my cousins and me against strangers.”

Bedouin proverb

At such times, cooperation can lead people to define a new, inclusive group that dissolves their former subgroups (Dovidio & Gaertner, 1999). If this were a social psychology experiment, you might seat members of two groups not on opposite sides, but alternately around a table. Give them a new, shared name. Have them work together. Then watch “us” and “them” become “we.” After 9/11, one 18-year-old New Jersey man described this shift in his own social identity: “I just thought of myself as Black. But now I feel like I’m an American, more than ever” (Sengupta, 2001). In a real experiment, White Americans who read a newspaper article about a terrorist threat against all Americans subsequently expressed reduced prejudice against Black Americans (Dovidio et al., 2004).

“Most of us have overlapping identities which unite us with very

different groups. We *can* love what we are, without hating what—and who—we are *not*. We can thrive in our own tradition, even as we learn from others.”

Kofi Annan, Nobel Peace Prize lecture, 2001.

Shawn Baldwin/AP Photo

If cooperative contact between rival group members encourages positive attitudes, might this principle bring people together in multicultural schools? Could cooperative learning in classrooms create interracial friendships, while also enhancing student achievement? Experiments with adolescents from 11 countries confirm that the answer is *Yes* (Roseth et al., 2008). In the classroom as in the sports arena, members of interracial groups who work together on projects typically come to feel friendly toward one another. Knowing this, thousands of teachers have made interracial cooperative learning part of their classroom experience.

The power of cooperative activity to make friends of former enemies has led psychologists to urge increased international exchange and cooperation. Some experiments have found that just imagining the shared threat of global climate change reduces international hostilities (Pyszczynski et al., 2012). From adjacent Brazilian tribes to European countries, formerly conflicting groups have managed to build interconnections, interdependence, and a

shared social identity as they seek common goals (Fry, 2012). As we engage in mutually beneficial trade, as we work to protect our common destiny on this fragile planet, and as we become more aware that our hopes and fears are shared, we can transform misperceptions that feed conflict into feelings of solidarity based on common interests.

COMMUNICATION When real-life conflicts become intense, a third-party mediator—a marriage counselor, labor mediator, diplomat, community volunteer—may facilitate much-needed communication (Rubin et al., 1994). Mediators help each party voice its viewpoint and understand the other's needs and goals. If successful, mediators can replace a competitive *win-lose* orientation with a cooperative *win-win* orientation that leads to a mutually beneficial resolution. A classic example: Two friends, after quarreling over an orange, agreed to split it. One squeezed his half for juice. The other used the peel from her half to flavor a cake. If only the two had communicated their motives to one another, they could have hit on the win-win solution of one having all the juice, the other all the peel.

Grant Hindsley/AP Photo

Superordinate goals override differences

Cooperative efforts to achieve shared goals are an effective way to break down social barriers.

CONCILIATION Understanding and cooperative resolution are most needed, yet least likely, in times of anger or crisis (Bodenhausen et al., 1994;

Tetlock, 1988). When conflicts intensify, images become more stereotyped, judgments more rigid, and communication more difficult, or even impossible. Each party is likely to threaten, coerce, or retaliate. In the weeks before the 1990 Gulf War, the first President George Bush threatened, in the full glare of publicity, to “kick Saddam’s ass.” Saddam Hussein communicated in kind, threatening to make Americans “swim in their own blood.”

Under such conditions, is there an alternative to war or surrender? Social psychologist Charles Osgood (1962, 1980) advocated a strategy of *Graduated and Reciprocated Initiatives in Tension-Reduction*, nicknamed **GRIT**. In applying GRIT, one side first announces its recognition of mutual interests and its intent to reduce tensions. It then initiates one or more small, conciliatory acts. Without weakening one’s retaliatory capability, this modest beginning opens the door for reciprocity by the other party. Should the enemy respond with hostility, one reciprocates in kind. But so, too, with any conciliatory response.

GRIT Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions.

In laboratory experiments, small conciliatory gestures—a smile, a touch, a word of apology—have allowed both parties to begin edging down the tension ladder to a safer rung where communication and mutual understanding can begin (Lindskold, 1978; Lindskold & Han, 1988). In a real-world international conflict, U.S. President John F. Kennedy’s gesture of stopping atmospheric nuclear tests began a series of reciprocated conciliatory acts that culminated in the 1963 atmospheric test-ban treaty.

As working toward shared goals reminds us, we are more alike than different. Civilization advances not by conflict and cultural isolation, but by tapping the knowledge, the skills, and the arts that are each culture’s legacy to the whole human race. Thanks to cultural sharing, our modern society has been enriched by our cultural mix (Sowell, 1991). We have China to thank for paper and printing and for the magnetic compass that opened the great explorations. We have Egypt to thank for trigonometry. We have the Islamic world and India’s Hindus to thank for our Arabic numerals. While celebrating and claiming these diverse cultural legacies, we can also welcome

the continuing enrichment of today's cultural diversity. We can view ourselves as instruments in a human orchestra. And we—including you, our worldwide readers—can therefore each affirm our own culture's heritage while building bridges of communication, understanding, and cooperation across our cultural traditions.

Warren Miller The New Yorker Collection/The Cartoon Bank

"To begin with, I would like to express my sincere thanks and deep appreciation for the opportunity to meet with you. While there are still profound differences between us, I think the very fact of my presence here today is a major breakthrough."

RETRIEVAL PRACTICE

RP-20 What are some ways to reconcile conflicts and promote peace?

ANSWER: Peacemakers should encourage equal-status contact, cooperation to achieve *superordinate goals* (shared goals that override differences), understanding through communication, and reciprocated conciliatory gestures (each side gives a little).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

The more familiar a stimulus becomes, the more we tend to like it. This exemplifies the _____ effect.

A happy couple celebrating their fiftieth wedding anniversary is likely to experience deep _____ love, even though their _____ love has probably decreased over the years.

After vigorous exercise, you meet an attractive person, and you are suddenly seized by romantic feelings for that person. This response supports the two-factor theory of emotion, which assumes that emotions, such as passionate love, consist of physical arousal plus

- a. a reward.
- b. proximity.
- c. companionate love.
- d. our interpretation of that arousal.

The bystander effect states that a particular bystander is less likely to give aid if

- a. the victim is similar to the bystander in appearance.
- b. no one else is present.
- c. other people are present.
- d. the incident occurs in a deserted or rural area.

Our enemies often have many of the same negative impressions of us as we have of them. This exemplifies the concept of

_____ - _____ perceptions.

One way of resolving conflicts and fostering cooperation is by giving rival groups shared goals that help them override their differences.

These are called _____ goals.

THINKING CRITICALLY ABOUT: The Stigma of Introversion

Social-Cognitive Theories and the Self

Social-Cognitive Theories

Exploring the Self

Lady Gaga dazzles millions with her unique musical arrangements, tantalizing outfits, and provocative performances. In shows worldwide, Lady Gaga's most predictable feature is her unpredictability. She has worn a meat dress to an award show, sported 16-inch heels to meet with U.S. President Barack Obama (who later described the interaction as "a little intimidating"), and inspired Super Bowl viewers with her halftime musical performance.

Yet even unpredictable Lady Gaga exhibits distinctive and enduring ways of thinking, feeling, and behaving. Her fans and critics alike can depend on her openness to new experiences and the energy she gets from the spotlight. And they can also rely on her painstaking dedication to her music and performances. She describes her high school self as "very dedicated, very studious, and very disciplined." Now, in adulthood, she shows similar self-discipline: "I'm very detailed—every minute of the show has got to be perfect." This chapter focuses on the ways we all demonstrate unique and persistent patterns of thinking, feeling, and behaving—our *personality*.

Much of this book deals with personality. Earlier chapters considered biological influences on personality; personality development across the life span; how personality relates to learning, motivation, emotion, and health; and social influences on personality. The next chapter will study disorders of personality. This chapter focuses on personality itself—what it is and how researchers study it.

We begin with two historically important theories of personality that have become part of Western culture: Sigmund Freud's *psychoanalytic theory* and *humanistic theories*. These sweeping perspectives on human nature laid the foundation for later personality theorists and for what this chapter presents next: newer scientific explorations of personality.

Today's personality researchers study the basic dimensions of personality, and the interaction of persons and environments. They also study self-esteem, self-serving bias, and cultural influences on our concept of self—that sense of "Who I am." And they study the unconscious mind—with findings that probably would have surprised even Freud.

Introduction to Personality and Psychodynamic Theories

What Is Personality?

LOQ **LEARNING OBJECTIVE QUESTION** **14-1** What is *personality*, and what theories inform our understanding of personality?

Psychologists have varied ways to view and study **personality**—our characteristic pattern of thinking, feeling, and acting. Sigmund Freud’s *psychoanalytic theory* proposed that childhood sexuality and unconscious motivations influence personality. The *humanistic theories* focused on our inner capacities for growth and self-fulfillment. Later theorists built upon these two broad perspectives. *Trait theories* examine characteristic patterns of behavior (*traits*). *Social-cognitive theories* explore the interaction between people’s traits (including their thinking) and their social context. Let’s begin with psychodynamic theories.

personality an individual’s characteristic pattern of thinking, feeling, and acting.

Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

Sigmund Freud (1856–1939)

“I was the only worker in a new field.”

Psychodynamic Theories

Psychodynamic theories of personality view human behavior as a dynamic interaction between the conscious mind and unconscious mind, including associated motives and conflicts. These theories are descended from Freud’s **psychoanalysis**—his theory of personality and the associated treatment techniques. Freud was the first to focus clinical attention on our unconscious mind.

psychodynamic theories theories that view personality with a focus on the unconscious and the importance of childhood experiences.

psychoanalysis Freud’s theory of personality that attributes thoughts and actions to unconscious motives and conflicts; the techniques used in treating psychological disorders by seeking to expose and interpret unconscious tensions.

Freud's Psychoanalytic Perspective: Exploring the Unconscious

LOQ 14-2 How did Sigmund Freud's treatment of psychological disorders lead to his view of the unconscious mind?

Ask 100 people on the street to name a notable deceased psychologist, suggested Keith Stanovich (1996, [p. 1](#)), and “Freud would be the winner hands down.” In the popular mind, he is to psychology what Elvis Presley is to rock music. Freud's influence lingers not only in psychiatry and clinical psychology, but also in literary and film interpretation. Almost 9 in 10 American college courses that reference psychoanalysis have been outside of psychology departments (Cohen, 2007). Freud's early twentieth-century concepts penetrate our twenty-first-century language. Without realizing their source, we may speak of *ego*, *repression*, *projection*, *complex* (as in “inferiority complex”), *sibling rivalry*, *Freudian slips*, and *fixation*. So, who was Freud, and what did he teach?

Like all of us, Sigmund Freud was a product of his times. His late 1800s Victorian era was a time of tremendous discovery and scientific advancement, but also of sexual suppression and male dominance. Men's and women's roles were clearly defined, with male superiority assumed and only male sexuality generally acknowledged (discreetly). These assumptions influenced Freud's thinking about personality. He believed that psychological troubles resulted from men's and women's unresolved conflicts with their expected roles.

“The female . . . acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs.”

Sigmund Freud, *Female Sexuality*, 1931

Long before entering the University of Vienna in 1873, young Freud showed signs of independence and brilliance. He so loved reading plays, poetry, and philosophy that he once ran up a bookstore debt beyond his means. As a teen he often took his evening meal in his tiny bedroom in order to lose no time from his studies. After medical school he set up a private

practice specializing in nervous disorders. Before long, however, he faced patients whose disorders made no neurological sense. A patient might have lost all feeling in a hand—yet there is no sensory nerve that, if damaged, would numb the entire hand and nothing else. Freud’s search for a cause for such disorders set his mind running in a direction destined to change human self-understanding.

Do some neurological disorders have psychological causes? Observing patients led Freud to his “discovery” of the **unconscious**. He speculated that lost feeling in one’s hand might be caused by a fear of touching one’s genitals; that unexplained blindness or deafness might be caused by not wanting to see or hear something that aroused intense anxiety. After some early unsuccessful trials with hypnosis, Freud turned to **free association**, in which he told the patient to relax and say whatever came to mind, no matter how embarrassing or trivial. He assumed that a line of mental dominoes had fallen from his patients’ distant past to their troubled present. Free association, he believed, would allow him to retrace that line, following a chain of thought leading into the patient’s unconscious. There, painful unconscious memories, often from childhood, could be retrieved, reviewed, and released.

unconscious according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware.

free association in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing.

Basic to Freud’s theory was his belief that the mind is mostly hidden (**FIGURE 14.1**). Our *conscious* awareness is like the part of an iceberg that floats above the surface. Beneath this awareness is the larger *unconscious* mind, with its thoughts, wishes, feelings, and memories. Some of these thoughts we store temporarily in a *preconscious* area, from which we can retrieve them into conscious awareness. Of greater interest to Freud was the mass of unacceptable passions and thoughts that he believed we *repress*, or forcibly block from our consciousness because they would be too unsettling

to acknowledge. Freud believed that without our awareness, these troublesome feelings and ideas powerfully influence us, sometimes gaining expression in disguised forms—the work we choose, the beliefs we hold, our daily habits, our upsetting symptoms.

FIGURE 14.1 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 14.1 Freud's idea of the mind's structure

Psychologists have used an iceberg image to illustrate Freud's idea that the mind is mostly hidden beneath the conscious surface. Note that the *id* is totally unconscious, but *ego* and *superego* operate both consciously and unconsciously. Unlike the parts of a frozen iceberg, however, the *id*, *ego*, and *superego* interact.

PERSONALITY STRUCTURE

LOQ 14-3 What was Freud's view of personality?

Freud believed that human personality, including its emotions and strivings, arises from a conflict between impulse and restraint—between our aggressive, pleasure-seeking biological urges and our internalized social controls over these urges. Freud believed personality arises from our efforts to resolve this basic conflict—to express these impulses in ways that bring satisfaction without also bringing guilt or punishment. To understand the mind's dynamics during this conflict, Freud proposed three interacting

systems: the *id*, *ego*, and *superego* ([Figure 14.1](#)).

"Fifty is plenty." "Hundred and fifty."
Bill Woodman The New Yorker Collection/
The Cartoon Bank

The ego struggles to reconcile the demands of superego and id, said Freud.

The **id's** unconscious psychic energy constantly strives to satisfy basic drives to survive, reproduce, and aggress. The id operates on the *pleasure principle*: It seeks immediate gratification. To understand the id's power, think of a newborn infant crying out for satisfaction, caring nothing for the outside world's conditions and demands. Or think of people with a present rather than future time perspective—those who heavily use tobacco, alcohol, or other drugs, and would sooner party now than sacrifice today's temporary pleasure for future success and happiness (Fernie et al., 2013; Friedel et al., 2014; Keough et al., 1999).

id a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure*

principle, demanding immediate gratification.

As the **ego** develops, the young child responds to the real world. The ego, operating on the *reality principle*, seeks to gratify the id's impulses in realistic ways that will bring long-term pleasure. (Imagine what would happen if, lacking an ego, we acted on our unrestrained sexual or aggressive impulses.) The ego contains our partly conscious perceptions, thoughts, judgments, and memories.

ego the largely conscious, “executive” part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id's desires in ways that will realistically bring pleasure rather than pain.

Around age 4 or 5, Freud theorized, a child's ego recognizes the demands of the newly emerging **superego**, the voice of our moral compass (conscience) that forces the ego to consider not only the real but also the *ideal*. The superego focuses on how we *ought* to behave. It strives for perfection, judging actions and producing positive feelings of pride or negative feelings of guilt. Someone with an exceptionally strong superego may be virtuous yet guilt ridden; another with a weak superego may be outrageously self-indulgent and remorseless.

superego the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations.

Because the superego's demands often oppose the id's, the ego struggles to reconcile the two. The ego is the personality “executive,” mediating among the impulsive demands of the id, the restraining demands of the superego, and the real-life demands of the external world. If chaste Conner feels sexually attracted to Tatiana, his ego may satisfy both his id and superego by joining a volunteer organization that Tatiana attends regularly.

To review Freud's components of personality, try the online **Concept Practice: Freud's Personality Structure**.

PERSONALITY DEVELOPMENT

LOQ 14-4 What developmental stages did Freud propose?

Analysis of his patients' histories convinced Freud that personality forms during life's first few years. He concluded that children pass through a series of **psychosexual stages**, during which the id's pleasure-seeking energies focus on distinct pleasure-sensitive areas of the body called *erogenous zones* (**TABLE 14.1**). Each stage offers its own challenges, which Freud saw as conflicting tendencies.

psychosexual stages the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones.

TABLE 14.1

Freud's Psychosexual Stages

Stage	Focus
<i>Oral</i> (0–18 months)	Pleasure centers on the mouth—sucking, biting, chewing
<i>Anal</i> (18–36 months)	Pleasure focuses on bowel and bladder elimination; coping with demands for control
<i>Phallic</i> (3–6 years)	Pleasure zone is the genitals; coping with incestuous sexual feelings
<i>Latency</i> (6 to puberty)	A phase of dormant sexual feelings
<i>Genital</i> (puberty on)	Maturation of sexual interests

"I heard that as soon as we become aware of our sexual impulses, whatever they are, we'll have to hide them."

Sidney Harris/Science Cartoons Plus

Freud believed that during the *phallic stage*, for example, boys develop both unconscious sexual desires for their mother and jealousy and hatred for their father, whom they consider a rival. These feelings, he thought, lead boys to feel guilty and to fear punishment, perhaps by castration, from their father. Freud called this collection of feelings the **Oedipus complex** after the Greek legend of Oedipus, who unknowingly killed his father and married his mother. Some psychoanalysts in Freud's era believed that girls experience a parallel *Electra complex* (named after a mythological plotting daughter).

Oedipus [ED-uh-puss] complex according to Freud, a boy's sexual desires toward his mother and feelings of jealousy and hatred for the rival father.

Children eventually cope with the threatening feelings, said Freud, by repressing them and by identifying with (trying to become like) the rival parent. It's as though something inside the child decides, "If you can't beat 'em [the same-sex parent], join 'em." Through this **identification** process, children's superegos gain strength as they incorporate many of their parents' values. Freud believed that identification with the same-sex parent provided what psychologists now call our *gender identity*—our sense of being male, female, or some combination of the two. Freud presumed that our early childhood relations—especially with our parents and other caregivers—

influence our developing identity, personality, and frailties.

identification the process by which, according to Freud, children incorporate their parents' values into their developing superegos.

In Freud's view, conflicts unresolved during earlier psychosexual stages could surface as maladaptive behavior in the adult years. At any point in the oral, anal, or phallic stages, strong conflict could lock, or **fixate**, the person's pleasure-seeking energies in that stage. A person who had been either orally overindulged or deprived (perhaps by abrupt, early weaning) might fixate at the oral stage. This orally fixated adult could exhibit either passive dependence (like that of a nursing infant) or an exaggerated denial of this dependence (by acting tough or uttering biting sarcasm). Or the person might continue to seek oral gratification by smoking or excessive eating. In such ways, Freud suggested, the twig of personality is bent at an early age.

fixation in personality theory, according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved.

"Oh, for goodness' sake! Smoke!"

Charles Saxon The New Yorker Collection/
The Cartoon Bank

DEFENSE MECHANISMS

LOQ 14-5 How did Freud think people defended themselves against anxiety?

Anxiety, said Freud, is the price we pay for civilization. As members of social groups, we must control our sexual and aggressive impulses, not act them out. But sometimes the ego fears losing control of this inner id-superego war. The presumed result is a dark cloud of unfocused anxiety that leaves us feeling unsettled but unsure why.

Freud proposed that the ego protects itself with **defense mechanisms** —tactics that reduce or redirect anxiety by distorting reality (**TABLE 14.2**). For Freud, *all defense mechanisms function indirectly and unconsciously*. Just as the body unconsciously defends itself against disease, so also does the ego unconsciously defend itself against anxiety. For example, **repression** banishes anxiety-arousing wishes and feelings from consciousness. According to Freud, *repression underlies all the other defense mechanisms*. However, because repression is often incomplete, repressed urges may appear as symbols in dreams or as slips of the tongue in casual conversation.

defense mechanisms in psychoanalytic theory, the ego's protective methods

of reducing anxiety by unconsciously distorting reality.

repression in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories.

TABLE 14.2

Six Defense Mechanisms

Freud believed that *repression*, the basic mechanism that banishes anxiety-arousing impulses, enables other defense mechanisms, six of which are listed here.

Defense Mechanism	Unconscious Process Employed to Avoid Anxiety-Arousing Thoughts or Feelings	Example
<i>Regression</i>	Retreating to an earlier psychosexual stage, where some psychic energy remains fixated	A little boy reverts to the oral comfort of thumb sucking in the car on the way to his first day of school.
<i>Reaction formation</i>	Switching unacceptable impulses into their opposites	Repressing angry feelings, a person displays exaggerated friendliness.
<i>Projection</i>	Disguising one's own threatening impulses by attributing them to others	"The thief thinks everyone else is a thief" (an El Salvadoran saying).
<i>Rationalization</i>	Offering self-justifying explanations in place of the	A habitual drinker says she drinks with her

	real, more threatening unconscious reasons for one's actions	friends "just to be sociable."
<i>Displacement</i>	Shifting sexual or aggressive impulses toward a more acceptable or less threatening object or person	A little girl kicks the family dog after her mother puts her in a time-out.
<i>Denial</i>	Refusing to believe or even perceive painful realities	A partner denies evidence of his loved one's affair.

Freud believed he could glimpse the unconscious seeping through when a financially stressed patient, not wanting any large pills, said, "Please do not give me any bills, because I cannot swallow them." (Today we call these "Freudian slips.") Freud also viewed jokes as expressions of repressed sexual and aggressive tendencies, and dreams as the "royal road to the unconscious." The remembered content of dreams (their *manifest content*) he believed to be a censored expression of the dreamer's unconscious wishes (the dream's *latent content*). In his dream analyses, Freud searched for patients' inner conflicts.

"Good morning, beheaded—uh, I mean beloved."

Dana Fradon The New Yorker Collection/
The Cartoon Bank

“I remember your name perfectly but I just can’t think of your face.”

Oxford professor W. A. Spooner (1844–1930) famous for his linguistic flip-flops (*spoonerisms*).

Spooner rebuked one student for “fighting a liar in the quadrangle” and another who “hissed my mystery lecture,” adding “You have tasted two worms.”

RETRIEVAL PRACTICE

RP-1 According to Freud’s ideas about the three-part personality structure, the _____ operates on the *reality principle* and tries to balance demands in a way that produces long-term pleasure rather than pain; the _____ operates on the *pleasure principle* and seeks immediate gratification; and the _____ represents the voice of our internalized ideals (our *conscience*).

ANSWER: ego; id; superego.

RP-2 In the psychoanalytic view, conflicts unresolved during one of the psychosexual stages may lead to _____ at that stage.

ANSWER: fixation.

RP-3 Freud believed that our defense mechanisms operate _____ (consciously/unconsciously) and defend us against _____.

ANSWER: unconsciously; anxiety

VStock/Alamy; Richard I'Anson/Getty Images

Regression

Faced with a mild stressor, children and young orangutans seek protection and comfort from their caregivers. Freud might have interpreted these behaviors as regression, a retreat to an earlier developmental stage.

The Neo-Freudian and Later Psychodynamic Theorists

LOQ 14-6 Which of Freud's ideas did his followers accept or reject?

In a historical period when people rarely talked about sex, and certainly not unconscious desires for sex with one's parent, Freud's writings sparked intense debate. "In the Middle Ages, they would have burned me," observed Freud to a friend. "Now they are content with burning my books" (Jones, 1957). Despite the controversy, Freud attracted followers. Several young, ambitious physicians formed an inner circle around their strong-minded

leader. These pioneering psychoanalysts, whom we often call *neo-Freudians*, adopted Freud's interviewing techniques and accepted his basic ideas: the personality structures of id, ego, and superego; the importance of the unconscious; the childhood roots of personality; and the dynamics of anxiety and the defense mechanisms. But they broke off from Freud in two important ways. First, they placed more emphasis on the conscious mind's role in interpreting experience and in coping with the environment. And second, they doubted that sex and aggression were all-consuming motivations. Instead, they tended to emphasize loftier motives and social interactions.

Karen Horney

“The view that women are infantile and emotional creatures, and as such, incapable of responsibility and independence is the work of the masculine tendency to lower women’s self-respect” (*Feminine Psychology*, 1932).

Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

Carl Jung

“From the living fountain of instinct flows everything that is creative; hence the unconscious is the very source of the creative impulse” (*The Structure and Dynamics of the Psyche*, 1960).

Alfred Adler and Karen Horney [HORN-eye], for example, agreed with Freud that childhood is important. But they believed that childhood *social*,

not sexual, tensions are crucial for personality formation (Ferguson, 2003, 2015). Adler (who gave us the still popular *inferiority complex* idea) had struggled to overcome childhood illnesses and accidents. He believed that much of our behavior is driven by efforts to conquer childhood inferiority feelings that trigger our strivings for superiority and power. Horney said childhood anxiety triggers our desire for love and security. She also opposed Freud's assumptions that women have weak superegos and suffer "penis envy," and she attempted to balance his masculine bias.

Carl Jung [Yoong] started out a strong follower of Freud, but then veered off. Jung placed less emphasis on social factors and agreed with Freud that the unconscious exerts a powerful influence. But to Jung, the unconscious contains more than our repressed thoughts and feelings. He believed we also have a **collective unconscious**, a common reservoir of images, or *archetypes*, derived from our species' universal experiences. Jung said that the collective unconscious explains why, for many people, spiritual concerns are deeply rooted and why people in different cultures share certain myths and images. Most of today's psychologists discount the idea of inherited experiences. But they do believe that our shared evolutionary history shaped some universal dispositions, and that experience can leave *epigenetic* marks affecting gene expression (see [Chapter 4](#)).

collective unconscious Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history.

Freud died in 1939. Since then, some of his ideas have been incorporated into the diverse perspectives that make up modern psychodynamic theory. "Most contemporary [psychodynamic] theorists and therapists are not wedded to the idea that sex is the basis of personality," noted Drew Westen (1996). They "do not talk about ids and egos, and do not go around classifying their patients as oral, anal, or phallic characters." What they do assume, with Freud and with much support from today's psychological science, is that much of our mental life is unconscious. With Freud, they also assume that we often struggle with inner conflicts among our wishes, fears, and values, and that childhood shapes our personality and ways of becoming attached to others.

For a helpful 9-minute overview, view the **Video: Psychodynamic Theories of Personality**.

Assessing Unconscious Processes

LOQ 14-7 What are *projective tests*, how are they used, and what are some criticisms of them?

Personality tests reflect the basic ideas of particular personality theories. So, what might be the assessment tool of choice for someone working in the Freudian tradition?

Such a test would need to provide some sort of road into the unconscious—to unearth the residue of early childhood experiences, move beneath surface thoughts, and reveal hidden conflicts and impulses. Objective assessment tools, such as agree-disagree or true-false questionnaires, would be inadequate because they would merely tap the conscious surface.

Projective tests aim to provide this “psychological X-ray” by asking test-takers to describe an ambiguous image or tell a story about it. The clinician may presume that any hopes, desires, and fears that people see in the ambiguous image are projections of their own inner feelings or conflicts.

projective test a personality test, such as the Rorschach, that provides ambiguous images designed to trigger projection of one’s inner dynamics.

Henry Murray (1933) demonstrated a possible basis for such a test at a party hosted by his 11-year-old daughter. Murray engaged the children in a frightening game called “Murder.” When shown some photographs after the game, the children perceived the photos as more malicious than they had before the game. These children, it seemed to Murray, had *projected* their inner feelings into the pictures.

A few years later, Murray introduced the **Thematic Apperception Test (TAT)**—a test in which people view ambiguous pictures and then make up stories about them. Shown a daydreaming boy, those who imagine he is fantasizing about an achievement are presumed to be projecting their own

goals. “As a rule,” said Murray, “the subject leaves the test happily unaware that he has presented the psychologist with what amounts to an X-ray of his inner self” (quoted by Talbot, 1999).

Thematic Apperception Test (TAT) a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes.

Numerous studies suggest that Murray was right: the TAT provides a valid and reliable map of people’s implicit motives. For example, such storytelling has been used to assess *achievement* and *affiliation motivation* (Drescher & Schultheiss, 2016; Schultheiss et al., 2014). TAT responses also show consistency over time (Lundy, 1985; Schultheiss & Pang, 2007). Show people a picture today, and they’ll imagine a story similar to one they will tell when, a month later, they see the same picture.

Swiss psychiatrist Hermann Rorschach [ROAR-shock; 1884–1922] created the most widely used projective test. He based his famous **Rorschach inkblot test**, in which people describe what they see in a series of inkblots (**FIGURE 14.2**), on a childhood game. He and his friends would drip ink on a paper, fold it, and then say what they saw in the resulting blot (Sdorow, 2005). Do you see predatory animals or weapons? Perhaps you have aggressive tendencies. But is this a reasonable assumption? The answer varies.

Rorschach inkblot test the most widely used projective test; a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people’s inner feelings by analyzing their interpretations of the blots.

FIGURE 14.2 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers
Spencer Grant/Science Source

FIGURE 14.2 The Rorschach test

In this projective test, people tell what they see in a series of symmetrical inkblots. Some who use this test are confident that the interpretation of ambiguous images will reveal unconscious aspects of the test-taker's personality.

“We don’t see things as they are; we see things as we are.”

The Talmud

Some clinicians cherish the Rorschach test, even offering Rorschach-based assessments of criminals’ violence potential. Others view the test as a source of suggestive leads, an icebreaker, or a revealing interview technique. The Society for Personality Assessment (2005) commends the test’s “responsible use” when “appropriate and justified” (which would *not* include, for example, using the test to infer past childhood sexual abuse).

But the evidence does not persuade its revilers, who insist the Rorschach is no emotional MRI. They argue that only a few of the many Rorschach-derived scores, such as those for cognitive impairment and thought disorder, have demonstrated reliability and validity (Mihura et al., 2013, 2015; Wood et al., 2015). And inkblot assessments have inaccurately diagnosed many healthy adults as pathological (Wood, 2003; Wood et al., 2006). “Even seasoned professionals can be fooled by their intuitions and their faith in

tools that lack strong evidence of effectiveness,” warned Scott Lilienfeld, James Wood, and Howard Garb (2001, [p. 47](#)). “When a substantial body of research demonstrates that old intuitions are wrong, it is time to adopt new ways of thinking.”

“The Rorschach [Inkblot Test] has the dubious distinction of being, simultaneously, the most cherished and the most reviled of all psychological assessment tools.”

John Hunsley and J. Michael Bailey (1999)

Evaluating Freud’s Psychoanalytic Perspective and Modern Views of the Unconscious

LOQ 14-8 How do contemporary psychologists view Freud’s psychoanalysis?

MODERN RESEARCH CONTRADICTS MANY OF FREUD’S IDEAS

We critique Freud from a twenty-first-century perspective. Freud did not have access to neurotransmitter or DNA studies, or to all that we have since learned about human development, thinking, and emotion. To criticize his theory by comparing it with today’s thinking is like criticizing Henry Ford’s Model T by comparing it with Elon Musk’s Tesla Model S. How tempting it always is to judge the past from the perspective of our present.

“Many aspects of Freudian theory are indeed out of date, and they should be: Freud died in 1939, and he has been slow to undertake further revisions.”

Psychologist Drew Westen (1998)

Nevertheless, both Freud’s devotees and his detractors agree that recent research contradicts many of his specific ideas. Today’s developmental psychologists see our *development as lifelong*, not fixed in childhood. They doubt that infants’ neural networks are mature enough to sustain as much emotional trauma as Freud assumed. Some think Freud overestimated

parental influence and underestimated peer influence. They also doubt that conscience and gender identity form as the child resolves the Oedipus complex at age 5 or 6. We gain our gender identity earlier, and those who become strongly masculine or feminine do so even without a same-sex parent present. And they note that Freud's ideas about childhood sexuality arose from stories of childhood sexual abuse told by his female patients—stories that some scholars believe Freud doubted, and attributed to his patients' own childhood sexual wishes and conflicts (Esterson, 2001; Powell & Boer, 1994). Today, we know that *childhood sexual abuse happens*, and we also understand how Freud's questioning might have created false memories of abuse.

Modern dream research disputes Freud's belief that dreams disguise and fulfill wishes. And slips of the tongue can be explained as competition between similar verbal choices in our memory network. Someone who says "I don't want to do that—it's a lot of brothel" may simply be blending *bother* and *trouble* (Foss & Hakes, 1978). Researchers find little support for Freud's idea that defense mechanisms disguise sexual and aggressive impulses (though our cognitive gymnastics do indeed work to protect our self-esteem). History also has failed to support another of Freud's ideas—that suppressed sexuality causes psychological disorders. From Freud's time to ours, sexual inhibition has diminished; psychological disorders have not.

Psychologists further criticize Freud's theory for its scientific shortcomings. Recall from [Chapter 1](#) that good scientific theories explain observations and offer testable hypotheses. Freud's theory rests on few objective observations, and parts of it offer few testable hypotheses. For Freud, his own recollections and interpretations of patients' free associations, dreams, and slips—sometimes selected to support his theory—were evidence enough.

What is the most serious problem with Freud's theory? It offers after-the-fact explanations of any characteristic (of one person's smoking, another's fear of horses, another's sexual orientation), yet fails to *predict* such behaviors and traits. If you feel angry at your mother's death, you illustrate Freud's theory because "your unresolved childhood dependency needs are threatened." If you do not feel angry, you again illustrate his theory because "you are repressing your anger." That "is like betting on a horse after the race has been run" (Hall & Lindzey, 1978, [p. 68](#)). A good theory makes testable

predictions.

“We are arguing like a man who should say, ‘If there were an invisible cat in that chair, the chair would look empty; but the chair does look empty; therefore there is an invisible cat in it’.”

C. S. Lewis, *Four Loves*, 1958

So, should psychology post an “Allow Natural Death” order on this old theory? Freud’s supporters object. To criticize Freudian theory for not making testable predictions is, they say, like criticizing baseball for not being an aerobic exercise—something it was never intended to be. Freud never claimed that psychoanalysis was predictive science. He merely claimed that, looking back, psychoanalysts could find meaning in our state of mind (Rieff, 1979).

Freud’s supporters also note that some of his ideas *are* enduring. It was Freud who drew our attention to the unconscious and the irrational, at a time when such ideas were not popular. Today, many researchers study our irrationality (Ariely, 2010; Thaler, 2015). Psychologist Daniel Kahneman won a 2002 Nobel Prize for his studies of our faulty decision making. Freud also drew our attention to the importance of human sexuality, and to the tension between our biological impulses and our social well-being. It was Freud who challenged our self-righteousness, exposed our self-protective defenses, and reminded us of our potential for evil.

“Although [Freud] clearly made a number of mistakes in the formulation of his ideas, his understanding of unconscious mental processes was pretty much on target. In fact, it is very consistent with modern neuroscientists’ belief that most mental processes are unconscious.”

Nobel Prize–winning neuroscientist Eric Kandel (2012)

MODERN RESEARCH CHALLENGES THE IDEA OF REPRESSION

Psychoanalytic theory hinges on the assumption that our mind often *represses* offending wishes, banishing them into the unconscious until they resurface, like long-lost books in a dusty attic. Recover and resolve

childhood's conflicted wishes, and emotional healing should follow. Repression became a widely accepted concept, used to explain hypnotic phenomena and psychological disorders. Some psychodynamic followers extended repression to explain apparently lost and recovered memories of childhood traumas (Boag, 2006; Cheit, 1998; Erdelyi, 2006). In one survey, 88 percent of university students believed that painful experiences commonly get pushed out of awareness and into the unconscious (Garry et al., 1994).

Today's researchers agree that we sometimes preserve our self-esteem by neglecting threatening information (Green et al., 2008). Yet many contend that repression, if it ever occurs, is a rare mental response to terrible trauma. Even those who have witnessed a parent's murder or survived Nazi death camps have retained their unrepressed memories of the horror (Helmreich, 1992, 1994; Malmquist, 1986; Pennebaker, 1990). "Dozens of formal studies have yielded not a single convincing case of repression in the entire literature on trauma," concluded personality researcher John Kihlstrom (2006).

Some researchers do believe that extreme, prolonged stress, such as the stress some severely abused children experience, might disrupt memory by damaging the hippocampus (Schacter, 1996). But the far more common reality is that high stress and associated stress hormones *enhance* memory. Indeed, rape, torture, and other traumatic events haunt survivors, who experience unwanted flashbacks. They are seared onto the soul. "You see the babies," said Holocaust survivor Sally H. (1979). "You see the screaming mothers. You see hanging people. You sit and you see that face there. It's something you don't forget."

"During the Holocaust, many children . . . were forced to endure the unendurable. For those who continue to suffer [the] pain is still present, many years later, as real as it was on the day it occurred."

Eric Zillmer, Molly Harrower, Barry Ritzler, and Robert Archer, *The Quest for the Nazi Personality*, 1995

For a helpful 13-minute exploration, see the **Video—Repression: Reality or Myth?**

THE MODERN UNCONSCIOUS MIND

LOQ 14-9 How has modern research developed our understanding of the unconscious?

Freud was right about a big idea that underlies today's psychodynamic thinking: We have limited access to all that goes on in our mind (Erdelyi, 1985, 1988, 2006; Norman, 2010). Our two-track mind has a vast out-of-sight realm. Some researchers even argue that "most of a person's everyday life is determined by unconscious thought processes" (Bargh & Chartrand, 1999). (Perhaps, for example, you can recall being sad or mad without consciously knowing why.)

Yet many research psychologists now think of the unconscious not as seething passions and repressive censoring but as cooler information processing that occurs without our awareness. To these researchers, the unconscious also involves (as we see elsewhere in this text):

- the *schemas* that automatically control our perceptions and interpretations ([Chapter 6](#)).
- the *priming* by stimuli to which we have not consciously attended ([Chapters 6](#) and [8](#)).
- the right-hemisphere activity that enables the *split-brain* patient's left hand to carry out an instruction the patient cannot verbalize ([Chapter 2](#)).
- the *implicit memories* that operate without conscious recall, even among those with amnesia ([Chapter 8](#)).
- the *emotions* that activate instantly, before conscious analysis ([Chapter 12](#)).
- the *stereotypes* and *implicit prejudice* that automatically and unconsciously influence how we process information about others ([Chapter 13](#)).

More than we realize, we fly on autopilot. Our lives are guided by off-screen, out-of-sight, unconscious information processing. The unconscious mind is huge. However, our current understanding of unconscious information processing is more like the pre-Freudian view of an underground, unattended stream of thought from which spontaneous behavior and creative ideas surface (Bargh & Morsella, 2008).

Research also supports two of Freud's defense mechanisms. One study

demonstrated *reaction formation* (trading unacceptable impulses for their opposite) in men who reported strong anti-gay attitudes. Compared with those who did not report such attitudes, these anti-gay men experienced greater physiological arousal (assessed with a device that measured bloodflow to the penis) when watching videos of homosexual men having sex, even though they said the films did not make them sexually aroused (Adams et al., 1996). Likewise, some evidence suggests that people who unconsciously identify as homosexual—but who consciously identify as straight—report more negative attitudes toward gays (Weinstein et al., 2012).

Freud's *projection* (attributing our own threatening impulses to others) has also been confirmed. People do tend to see their traits, attitudes, and goals in others (Baumeister et al., 1998b; Maner et al., 2005). Today's researchers call this the *false consensus effect*—the tendency to overestimate the extent to which others share our beliefs and behaviors. People who binge-drink or break speed limits tend to think many others do the same. However, defense mechanisms seem motivated less by the sexual and aggressive undercurrents that Freud imagined than by our need to protect our self-image.

Finally, research has supported Freud's idea that we unconsciously defend ourselves against anxiety. Researchers have proposed that one source of anxiety is “the terror resulting from our awareness of vulnerability and death” (Greenberg et al., 1997). Nearly 300 experiments testing [terror-management theory](#) show that thinking about one's mortality—for example, by writing a short essay on dying and its associated emotions—provokes various terror-management defenses (Burke et al., 2010). For example, death anxiety increases aggression toward rivals and esteem for oneself (Cohen & Solomon, 2011; Koole et al., 2006).

terror-management theory a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death.

Faced with a threatening world, people act not only to enhance their self-esteem but also to adhere more strongly to worldviews that answer questions about life's meaning. The prospect of death promotes religious sentiments, and deep religious convictions enable people to be less defensive—less likely

to rise in defense of their worldview—when reminded of death (Jonas & Fischer, 2006; Norenzayan & Hansen, 2006). Moreover, when contemplating death, people prioritize their close relationships (Cox & Arndt, 2012; Mikulincer et al., 2003). The actual death of loved ones can provoke protective responses as well. For years, I [ND] have studied the way people respond to thoughts about death—but it took the shock of my own mother’s unexpected death to motivate me to start running again, and to live a healthier lifestyle (Hayasaki, 2014; Kashdan et al., 2014). Facing death can inspire us to affirm life.

"It says, 'Someday you will die.'"

RETRIEVAL PRACTICE

RP-4 What are three big ideas that have survived from Freud’s psychoanalytic theory? What are three ways in which Freud’s theory has been criticized?

ANSWER: Freud is credited with first drawing attention to (1) the importance of childhood experiences, (2) the existence of the unconscious mind, and (3) our self-protective defense mechanisms. Freud’s theory has been criticized as (1) not scientifically testable and offering after-the-fact explanations, (2) focusing too much on sexual conflicts in childhood, and (3) being based on the idea of repression, which has not been supported by modern research.

RP-5 Which elements of traditional psychoanalysis have modern-day *psychodynamic* theorists and therapists retained, and which elements have they mostly left behind?

ANSWER: Today's psychodynamic theorists and therapists still rely on the interviewing techniques that Freud used, and they still tend to focus on childhood experiences and attachments, unresolved conflicts, and unconscious influences. However, they are not likely to dwell on fixation at any psychosexual stage, or the idea that sexual issues are the basis of our personality.

REVIEW Introduction to Personality and Psychodynamic Theories

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Freud believed that we may block painful or unacceptable thoughts, wishes, feelings, or memories from consciousness through an unconscious process called _____.

According to Freud's view of personality structure, the "executive" system, the _____, seeks to gratify the impulses of the _____ in more acceptable ways.

- a. id; ego
- b. ego; superego
- c. ego; id
- d. id; superego

Freud proposed that the development of the "voice of our moral compass" is related to the _____, which internalizes ideals and provides standards for judgments.

According to the psychoanalytic view of development, we all pass through a series of psychosexual stages, including the oral, anal, and phallic stages. Conflicts unresolved at any of these stages may lead to

- a. dormant sexual feelings.
- b. fixation at that stage.
- c. preconscious blocking of impulses.
- d. a distorted gender identity.

Freud believed that defense mechanisms are unconscious attempts to distort or disguise reality, all in an effort to reduce our _____.

_____ tests ask test-takers to respond to an ambiguous image by describing it or telling a story about it.

In general, neo-Freudians such as Adler and Horney accepted many of Freud's views but placed more emphasis than he did on

- a. development throughout the life span.
- b. the collective unconscious.
- c. the role of the id.

d. social interactions.

Modern-day psychodynamic theorists and therapists agree with Freud about

- a. the existence of unconscious mental processes.
- b. the Oedipus complex.
- c. the predictive value of Freudian theory.
- d. the superego's role as the executive part of personality.

Which of the following is NOT part of the contemporary view of the unconscious?

- a. Repressed memories of anxiety-provoking events
- b. Schemas that influence our perceptions and interpretations
- c. Stereotypes that affect our information processing
- d. Instantly activated emotions and implicit memories of learned skills

Answers are a click away in the e-book, and in [Appendix D](#) at the back of the printed text.

Humanistic Theories and Trait Theories

Humanistic Theories

LOQ 14-10 How did humanistic psychologists view personality, and what was their goal in studying personality?

By the 1960s, some personality psychologists had become discontented with the sometimes bleak focus on drives and conflicts in psychodynamic theory, and the mechanistic psychology of B. F. Skinner's *behaviorism* (see [Chapter 7](#)). Two pioneering theorists—Abraham Maslow (1908–1970) and Carl Rogers (1902–1987)—offered a *third-force perspective* that emphasized our potential for healthy personal growth. In contrast to Sigmund Freud's emphasis on disorders born out of dark conflicts, these [humanistic theorists](#) emphasized the ways people strive for self-determination and self-realization. In contrast to behaviorism's scientific objectivity, they studied people through their own self-reported experiences and feelings.

humanistic theories theories that view personality with a focus on the potential for healthy personal growth.

Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

Abraham Maslow

“Any theory of motivation that is worthy of attention must deal with the highest capacities of the healthy and strong person as well as with the defensive maneuvers of crippled spirits” (*Motivation and Personality*, 1970, [p. 33](#)).

Abraham Maslow's Self-Actualizing Person

Maslow proposed that we are motivated by a [hierarchy of needs](#) ([Chapter 11](#)). If our physiological needs are met, we become concerned with personal safety. If we achieve a sense of security, we then seek to love, to be loved, and to love ourselves. With our love needs satisfied, we seek self-esteem. Having achieved self-esteem, we ultimately seek [self-actualization](#) (the process of fulfilling our potential) and [self-transcendence](#) (meaning, purpose, and identity beyond the self).

hierarchy of needs Maslow's pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active.

self-actualization according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential.

self-transcendence according to Maslow, the striving for identity, meaning,

and purpose beyond the self.

Maslow (1970) developed his ideas by studying healthy, creative people rather than troubled clinical cases. He based his description of self-actualization on a study of those, such as Abraham Lincoln, who seemed notable for their meaningful and productive lives. Maslow reported that such people shared certain characteristics: They were self-aware and self-accepting, open and spontaneous, loving and caring, and not paralyzed by others' opinions. Secure in their sense of who they were, their interests were problem-centered rather than self-centered. They focused their energies on a particular task, one they often regarded as their mission in life. Most enjoyed a few deep relationships rather than many superficial ones. Many had been moved by spiritual or personal *peak experiences* that surpassed ordinary consciousness. These, said Maslow, are mature adult qualities found in those who have learned enough about life to be compassionate, to have outgrown their mixed feelings toward their parents, to have found their calling, to have "acquired enough courage to be unpopular, to be unashamed about being openly virtuous."

Carl Rogers' Person-Centered Perspective

Fellow humanistic psychologist Carl Rogers agreed with much of Maslow's thinking. Rogers' *person-centered perspective* held that people are basically good and are endowed with self-actualizing tendencies. Unless thwarted by an environment that inhibits growth, each of us is like an acorn, primed for growth and fulfillment. Rogers (1980) believed that a growth-promoting social climate provides:

- **Acceptance:** When people are *accepting*, they offer unconditional positive regard, an attitude of grace that values us even knowing our failings. It is a profound relief to drop our pretenses, confess our worst feelings, and discover that we are still accepted. In a good marriage, a close family, or an intimate friendship, we are free to be spontaneous without fearing the loss of others' esteem.
- **Genuineness:** When people are *genuine*, they are open with their own feelings, drop their facades, and are transparent and self-

disclosing.

- **Empathy:** When people are *empathic*, they share and mirror other's feelings and reflect their meanings. "Rarely do we listen with real understanding, true empathy," said Rogers. "Yet listening, of this very special kind, is one of the most potent forces for change that I know."

unconditional positive regard a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help people develop self-awareness and self-acceptance.

"Just remember, son, it doesn't matter whether you win or lose—unless you want Daddy's love."

Pat Byrnes The New Yorker Collection/
The Cartoon Bank

A father *not* offering unconditional positive regard:

So, some things get better with *age*: acceptance, genuineness, and empathy. These are, Rogers believed, the water, sun, and nutrients that enable people to grow like vigorous oak trees. For "as persons are accepted and prized, they tend to develop a more caring attitude toward themselves" (Rogers, 1980, [p. 116](#)). As persons are empathically heard, "it becomes possible for them to listen more accurately to the flow of inner experiencings."

Writer Calvin Trillin (2006) recalled an example of parental acceptance

and genuineness at a camp for children with severe disorders, where his wife, Alice, worked. L., a “magical child,” had genetic diseases that meant she had to be tube-fed and could walk only with difficulty. Alice recalled,

One day, when we were playing duck-duck-goose, I was sitting behind her and she asked me to hold her mail for her while she took her turn to be chased around the circle. It took her a while to make the circuit, and I had time to see that on top of the pile [of mail] was a note from her mom. Then I did something truly awful. . . . I simply had to know what this child’s parents could have done to make her so spectacular, to make her the most optimistic, most enthusiastic, most hopeful human being I had ever encountered. I snuck a quick look at the note, and my eyes fell on this sentence: “If God had given us all of the children in the world to choose from, L., we would only have chosen you.” Before L. got back to her place in the circle, I showed the note to Bud, who was sitting next to me. “Quick. Read this,” I whispered. “It’s the secret of life.”

DYL AN MARTINEZ/REUTERS/Newscom

The picture of empathy

Being open and sharing confidences is easier when the listener shows real understanding. Within such relationships we can relax and fully express our true selves. Consider a conversation when you knew someone was waiting for their turn to speak instead of listening to you. Now consider the last time someone heard you with empathy. How did

those two experiences differ?

Maslow and Rogers would have smiled knowingly. For them, a central feature of personality is one's **self-concept**—all the thoughts and feelings we have in response to the question, “Who am I?” If our self-concept is positive, we tend to act and perceive the world positively. If it is negative—if in our own eyes we fall far short of our *ideal self*—said Rogers, we feel dissatisfied and unhappy. A worthwhile goal for therapists, parents, teachers, and friends is therefore, he said, to help others know, accept, and be true to themselves.

self-concept all our thoughts and feelings about ourselves, in answer to the question, “Who am I?”

To consider how this theory applies to your own life, try the online **Assess Your Strengths: What Is Your Self-Concept?**

Assessing the Self

LOQ 14-11 How did humanistic psychologists assess a person's sense of self?

Humanistic psychologists sometimes assessed personality by asking people to fill out questionnaires that would evaluate their self-concept. One questionnaire, inspired by Carl Rogers, asked people to describe themselves both as they would *ideally* like to be and as they *actually* are. When the ideal and the actual self are nearly alike, said Rogers, the self-concept is positive. Assessing his clients' personal growth during therapy, he looked for successively closer ratings of actual and ideal selves.

Some humanistic psychologists believed that any standardized assessment of personality, even a questionnaire, is depersonalizing. Rather than forcing the person to respond to narrow categories, these humanistic psychologists presumed that interviews and intimate conversation would provide a better understanding of each person's unique experiences. Some researchers believe our identity may be revealed using the *life story approach*—collecting a rich narrative detailing each person's unique life history (Adler et al., 2016;

McAdams & Guo, 2015). A lifetime of stories can show more of a person's complete identity than can the responses to a few questions.

Evaluating Humanistic Theories

LOQ 14-12 How have humanistic theories influenced psychology?

What criticisms have they faced?

One thing said of Freud can also be said of the humanistic psychologists: Their impact has been pervasive. Maslow's and Rogers' ideas have influenced counseling, education, child raising, and management. And they laid the groundwork for today's scientific *positive psychology* subfield ([Chapter 12](#)).

These theorists have also influenced—sometimes in unintended ways—much of today's popular psychology. Is a positive self-concept the key to happiness and success? Do acceptance and empathy nurture positive feelings about ourselves? Are people basically good and capable of self-improvement? Many people answer *Yes, Yes, and Yes*. In 2006, U.S. high school students reported notably higher self-esteem and greater expectations of future career success than did students living in 1975 (Twenge & Campbell, 2008). Given a choice, today's North American college students mostly say they'd rather get a self-esteem boost, such as a compliment or good grade on a paper, than enjoy a favorite food or sexual activity (Bushman et al., 2011). Humanistic psychology's message has been heard.

But the prominence of the humanistic perspective set off a backlash of criticism. First, said the critics, its concepts are vague and subjective. Consider Maslow's description of self-actualizing people as open, spontaneous, loving, self-accepting, and productive. Is this a scientific description? Or is it merely a description of the theorist's own values and ideals? Maslow, noted M. Brewster Smith (1978), offered impressions of his own personal heroes. Imagine another theorist who began with a different set of heroes—perhaps Napoleon, John D. Rockefeller, Sr., and U.S. President Donald Trump. This theorist might describe self-actualizing people as “undeterred by others' opinions,” “motivated to achieve,” and “comfortable with power.”

Critics also objected to the idea that, as Rogers (1985) put it, “The only

question which matters is, ‘Am I living in a way which is deeply satisfying to me, and which truly expresses me?’” This emphasis on *individualism*—trusting and acting on one’s feelings, being true to oneself, fulfilling oneself—could lead to self-indulgence, selfishness, and an erosion of moral restraint (Campbell & Specht, 1985; Wallach & Wallach, 1983). Imagine working on a group project with people who refuse to complete any task that is not deeply satisfying or does not truly express their identity.

Humanistic psychologists have replied that a secure, nondefensive self-acceptance is actually the first step toward loving others. Indeed, people who feel intrinsically liked and accepted—for who they are, not just for their achievements—exhibit less defensive attitudes (Schimmel et al., 2001). Those feeling liked and accepted by a romantic partner report being happier in their relationships and acting more kindly toward their partner (Gordon & Chen, 2010).

A final accusation leveled against humanistic psychology is that it is *naive*—that it fails to appreciate the reality of our human capacity for evil (May, 1982). Faced with climate change, overpopulation, terrorism, and the spread of nuclear weapons, we may become apathetic from either of two rationalizations. One is a starry-eyed optimism that denies the threat (“People are basically good; everything will work out”). The other is a dark despair (“It’s hopeless; why try?”). Action requires enough realism to fuel concern and enough optimism to provide hope. (Pessimism often fulfills its own predictions, by restraining our efforts at change.) Humanistic psychology, say the critics, encourages the needed hope but not the equally necessary realism about threats.

"We do pretty well when you stop to think that people are basically good."

The Cartoon Bank

RETRIEVAL PRACTICE

RP-6 How did the *humanistic theories* provide a fresh perspective?

ANSWER: The humanistic theories sought to turn psychology's attention away from drives and conflicts and toward our growth potential. This movement's focus on the way people strive for self-determination and self-realization was in contrast to Freudian theory and strict behaviorism.

RP-7 What does it mean to be *empathic*? How about *self-actualized*? Which humanistic psychologists used these terms?

ANSWER: To be *empathic* is to share and mirror another person's feelings. Carl Rogers believed that people nurture growth in others by being empathic. Abraham Maslow proposed that *self-actualization* is the motivation to fulfill one's potential, and one of the ultimate psychological needs (the other is self-transcendence).

Trait Theories

LOQ 14-13 How do psychologists use traits to describe personality?

Rather than focusing on unconscious forces and thwarted growth opportunities, some researchers attempt to define personality in terms of stable and enduring behavior patterns, such as Lady Gaga’s openness to new experiences and her self-discipline. This perspective can be traced in part to a remarkable meeting in 1919, when Gordon Allport, a curious 22-year-old psychology student, interviewed Sigmund Freud in Vienna. Allport soon discovered just how preoccupied the founder of psychoanalysis was with finding hidden motives, even in Allport’s own behavior during the interview. That experience ultimately led Allport to do what Freud did not do: to describe personality in terms of fundamental **traits**, or people’s characteristic behaviors and conscious motives (such as the curiosity that actually motivated Allport to see Freud). Meeting Freud, said Allport, “taught me that [psychoanalysis], for all its merits, may plunge too deep, and that psychologists would do well to give full recognition to manifest motives before probing the unconscious.” Allport came to define personality in terms of identifiable behavior patterns. He was concerned less with *explaining* individual traits than with *describing* them.

trait a characteristic pattern of behavior or a disposition to feel and act in certain ways, as assessed by self-report inventories and peer reports.

Like Allport, Isabel Briggs Myers (1987) and her mother, Katharine Briggs, wanted to describe important personality differences. They attempted to sort people according to Carl Jung’s *personality types*, based on their responses to 126 questions. The *Myers-Briggs Type Indicator (MBTI)*, available in 20+ languages, has been taken by millions of people, mostly for counseling, leadership training, and work-team development (CPP, 2017). It offers choices, such as “Do you usually value sentiment more than logic, or value logic more than sentiment?” Then it counts the test-taker’s preferences, labels them as indicating, say, a “feeling type” or “thinking type,” and feeds them back to the person in complimentary terms. Feeling types, for example, are told they are “sympathetic, appreciative, and tactful”; thinking types are

told they are “good at analyzing.” (Every type has its strengths, so everyone is affirmed.)

Most people agree with their announced MBTI profile, which mirrors their declared preferences. They may also accept their label as a basis for being matched with work partners and tasks that supposedly suit their temperaments. But research suggests that people should not blindly accept the validity of their test results. A National Research Council report noted that despite the test’s popularity in business and career counseling, its use has outrun research on its validity as a job performance predictor: “The popularity of this instrument in the absence of proven scientific worth is troublesome” (Druckman & Bjork, 1991, [p. 101](#); see also Pittenger, 1993). Although research on the MBTI has been accumulating since those cautionary words were expressed, the test remains mostly a counseling and coaching tool, not a research instrument.

Exploring Traits

Classifying people as one or another distinct personality type fails to capture their full individuality. We are each a unique complex of multiple traits. So how else could we describe our personalities? We might describe an apple by placing it along several trait dimensions—relatively large or small, red or green, sweet or tart. By placing people on several trait dimensions simultaneously, psychologists can describe countless individual personality variations. (Remember from [Chapter 6](#) that variations on just three color dimensions—*hue*, *saturation*, and *brightness*—create many thousands of colors.)

"Russ is the sort of person who never wants to be alone with his thoughts."

William Haefeli The New Yorker Collection/
The Cartoon Bank

What trait dimensions describe personality? If you were looking at profiles on an Internet dating site, what personality traits would give you the best sense for each person? Allport and his associate H. S. Odbert (1936) counted all the words in an unabridged dictionary with which one could describe people. There were almost 18,000! How, then, could psychologists condense the list to a manageable number of basic traits?

FACTOR ANALYSIS One technique is *factor analysis*, a statistical procedure that identifies clusters (factors) of test items that tap basic components of a trait (McCabe & Fleeson, 2016). Imagine that people who describe themselves as outgoing also tend to say that they like excitement and practical jokes and dislike quiet reading. Such a statistically correlated cluster of behaviors reflects a basic factor, or trait—in this case, *extraversion*.

British psychologists Hans Eysenck and Sybil Eysenck [EYE-zink] believed that we can reduce many of our normal individual variations to two dimensions: *extraversion–introversion* and *emotional stability–instability* (**FIGURE 14.3**). People in 35 countries around the world, from China to Uganda to Russia, have taken the *Eysenck Personality Questionnaire*. When their answers were analyzed, the extraversion and emotionality factors inevitably emerged as basic personality dimensions (Eysenck, 1990, 1992). The Eysencks believed, and research confirms, that these factors are

genetically influenced.

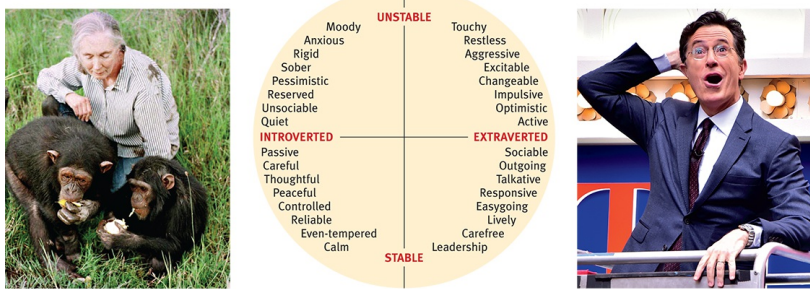

FIGURE 14.3 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Jean-Marc Bouju/AP Photo; James Devaney/Getty Images

FIGURE 14.3 Two personality dimensions

Mapmakers can tell us a lot by using two axes (north–south and east–west). Two primary personality factors (extraversion–introversion and stability–instability) are similarly useful as axes for describing personality variation. Varying combinations define other, more specific traits (Eysenck & Eysenck, 1963). Those who are naturally introverted, such as primatologist Jane Goodall, may be particularly gifted in field studies. Successful comedians, including Stephen Colbert, are often natural extraverts.

BIOLOGY AND PERSONALITY Brain-activity scans of extraverts add to the growing list of traits and mental states now being explored with brain-imaging procedures. Such studies indicate that extraverts seek stimulation because their normal brain arousal is relatively low. For example, PET scans have shown that a frontal lobe area involved in behavior inhibition is less active in extraverts than in introverts (Johnson et al., 1999). Dopamine and dopamine-related neural activity tend to be higher in extraverts (Kim et al., 2008; Wacker et al., 2006).

Our biology influences our personality in other ways as well. Recall from the twin and adoption studies in [Chapter 4](#) that our genes have much to say about the *temperament* and behavioral style that shape our personality. Jerome Kagan, for example, has attributed differences in children’s shyness and inhibition to their autonomic nervous system reactivity (see [Thinking Critically About: The Stigma of Introversion](#)). Those with a reactive autonomic nervous system respond to stress with greater anxiety and inhibition. The fearless, curious child may become the rock-climbing or fast-driving adult.

LOQ 14-14 What are some common misunderstandings about introversion?

Thinking Critically About: The Stigma of Introversion

Western cultures prize extraversion:

Superheroes tend to be extraverted: Superman is bold and energetic. His introverted alter ego, Clark Kent, is mild-mannered and bumbling.

Take-charge Elastigirl saves the day in *The Incredibles*.

87% of Westerners want to be more extraverted.¹

Being introverted seems to imply that we don't have the "right stuff."²

Attractive, successful people are presumed to be extraverts.

What is introversion?

Introversion is *not* shyness.
(Shy people remain quiet because they fear others will evaluate them negatively.)

Introverted people seek low levels of stimulation from their environment because they're *sensitive*. For example, when given lemon juice, introverted people salivated more than extraverted people.³

Introversion may have benefits:

- Introverted leaders outperform extraverted leaders in some contexts, such as when their employees voice new ideas and challenge existing norms.⁴
- An analysis of 35 studies showed no correlation between extraversion and sales performance.⁵
- Many introverts flourish, including Abraham Lincoln, Mother Teresa, and Gandhi.

Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

Personality differences among dogs (in energy, affection, reactivity, and curious intelligence) are as evident, and as consistently judged, as personality differences among humans (Gosling et al., 2003; Jones & Gosling, 2005). Monkeys, bonobos, chimpanzees, orangutans, and even birds and fish also have distinct and stable personalities (Latzman et al., 2015; Pennisi, 2016; Weiss et al., 2006, 2015). Among the Great Tit (a European relative of the American chickadee), bold birds more quickly inspect new objects and explore trees (Groothuis & Carere, 2005; Verbeek et al., 1994). Through selective breeding, researchers can produce bold or shy birds. Both have their place in natural history: In lean years, bold birds are more likely to find food; in abundant years, shy birds feed with less risk.

RP-8 Which two primary dimensions did Hans Eysenck and Sybil Eysenck propose for describing personality variation?

ANSWER: introversion–extraversion and emotional stability–instability

Assessing Traits

LOQ 14-15 What are *personality inventories*, and what are their strengths and weaknesses as trait-assessment tools?

If stable and enduring traits guide our actions, can we devise valid and reliable tests of them? Several trait assessment techniques exist—some more valid than others. Some provide quick assessments of a single trait, such as extraversion, anxiety, or self-esteem. [Personality inventories](#)—longer questionnaires covering a wide range of feelings and behaviors—assess several traits at once.

personality inventory a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits.

 Might astrology hold the secret to our personality traits? Consider this question by engaging online with **Immersive Learning: How Would You Know If Astrologers Can Describe People's Personality?**

The classic personality inventory is the [Minnesota Multiphasic Personality Inventory \(MMPI\)](#). Although the MMPI was originally developed to identify emotional disorders, it also assesses people's personality traits. One of its creators, Starke Hathaway (1960), compared his effort with that of Alfred Binet (who, as you may recall from [Chapter 10](#), developed the first intelligence test by selecting items that identified children who would

probably have trouble progressing normally in French schools). Like Binet's items, the MMPI items were **empirically derived**: From a large pool of items, Hathaway and his colleagues selected those on which particular diagnostic groups differed. "Nothing in the newspaper interests me except the comics" may seem superficial, but it just so happened that depressed people were more likely to answer *True*. The researchers grouped the questions into 10 clinical scales, including scales that assess depressive tendencies, masculinity–femininity, and intro–version–extraversion. Today's MMPI-2 has additional scales that assess work attitudes, family problems, and anger.

Minnesota Multiphasic Personality Inventory (MMPI) the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes.

empirically derived test a test (such as the MMPI) created by selecting from a pool of items those that discriminate between groups.

Whereas most projective tests (such as the Rorschach) are scored subjectively, personality inventories are scored objectively. Objectivity does not, however, guarantee validity. For example, individuals taking the MMPI for employment purposes can give socially desirable answers to create a good impression. But in so doing they may also score high on a *lie scale* that assesses faking (as when people respond *False* to a universally true statement such as "I get angry sometimes"). The objectivity of the MMPI has contributed to its popularity and its translation into more than 100 languages.

People have had fun spoofing the MMPI with their own mock items: "Weeping brings tears to my eyes," "Frantic screams make me nervous," and "I stay in the bathtub until I look like a raisin" (Frankel et al., 1983).

The Big Five Factors

LOQ 14-16 Which traits seem to provide the most useful information about personality variation?

Today’s trait researchers believe that simple trait factors, such as the Eysencks’ introversion–extraversion and stability–instability dimensions, are important, but they do not tell the whole story. A slightly expanded set of factors—dubbed the *Big Five*—does a better job (Costa & McCrae, 2011). If a test specifies where you are on the five dimensions (conscientiousness, agreeableness, neuroticism, openness, and extraversion; see [TABLE 14.3](#)), it has said much of what there is to say about your personality. Some clinical psychologists have begun to use the Big Five to understand personality disorder and dysfunction (Widiger et al., 2016).

TABLE 14.3

The “Big Five” Personality Factors

Researchers use self-report inventories and peer reports to assess and score the Big Five personality factors.

(Memory tip: Picturing a **CANOE** will help you recall these.)

Disorganized, careless, impulsive	← Conscientiousness →	Organized, careful, disciplined
Ruthless, suspicious, uncooperative	← Agreeableness →	Soft-hearted, trusting, helpful
Calm, secure, self-satisfied	← Neuroticism (emotional stability vs. instability) →	Anxious, insecure, self-pitying
Practical, prefers routine, conforming	← Openness →	Imaginative, prefers variety, independent
Retiring, sober, reserved	← Extraversion →	Sociable, fun-loving, affectionate

Information from McCrae & Costa (1986, 2008).

Steve Wildman/Getty Images

Around the world—across 56 nations and 29 languages in one study (Schmitt et al., 2007)—people describe others in terms roughly consistent with this list. The Big Five—today’s “common currency for personality psychology” (Funder, 2001)—has been the most active personality research topic since the early 1990s and is currently our best approximation of the basic trait dimensions.

Big Five research has explored various questions:

- ***How stable are these traits?*** One research team analyzed 1.25 million participants ages 10 to 65. They learned that personality continues to develop and change through late childhood and adolescence. Up to age 40, we show signs of a *maturity principle*: We become more conscientious and agreeable and less neurotic (emotionally unstable) (Bleidorn, 2015; Milojev & Sibley, 2016). Great apes show similar personality maturation (Weiss & King, 2015). After age 40, our traits further stabilize.
- ***How heritable are these traits?*** Heritability (the extent to which individual differences are attributable to genes) generally runs about 40 percent for each dimension (Vukasović & Bratko, 2015). Many genes, each having small effects, combine to influence our traits (McCrae et al., 2010; van den Berg et al., 2016).
- ***Do these traits reflect differing brain structure?*** The size and thickness of brain tissue correlates with several Big Five traits (DeYoung et al., 2010; Grodin & White, 2015; Riccelli et al., 2017). For example, those who score high on conscientiousness tend to have a larger frontal lobe area that aids in planning and controlling behavior. Brain connections also influence the Big Five traits (Adelstein et al., 2011). People high in neuroticism (emotional instability) have brains that are wired to experience stress intensely (Shackman et al., 2016; Xu et al., 2012).
- ***Do these traits reflect birth order?*** After controlling for other variables such as family size, are first-born children, for example, more conscientious and agreeable? Contrary to popular opinion, several massive studies failed to find any association between birth order and personality (Damian & Roberts, 2015; Harris, 2009; Rohrer et al., 2015).
- ***How well do these traits apply to various cultures?*** The Big Five dimensions describe personality in various cultures reasonably well (Fetvadjiev et al., 2017; Schmitt et al., 2007; Vazsonyi et al., 2015). After studying people from 50 cultures, Robert McCrae and 79 co-researchers concluded that “features of personality traits are common to all human groups” (2005).

- ***Do the Big Five traits predict our actual behaviors?*** Yes. If people report being outgoing, conscientious, and agreeable, “they probably are telling the truth,” reports McCrae (2011). Conscientiousness and agreeableness predict workplace success, and agreeableness predicts helpfulness (Habashi et al., 2016; Sackett & Walmsley, 2014). Traits also characterize certain career paths. For example, U.S. politicians tend to have “big” personalities, outscoring the general public on extraversion, agreeableness, conscientiousness, and emotional stability (low neuroticism) (Hanania, 2017). Our traits also appear in our language patterns. In text messaging, extraversion predicts use of personal pronouns. Neuroticism predicts negative-emotion words (Holtgraves, 2011).

Tom Pennington/Getty Images; KENA BETANCUR/Getty Images

How do you vote? Let me count the likes.

Researchers can use your Facebook likes to predict your Big Five traits, your opinions, and your political attitudes (Youyou et al., 2015). Companies gather these “big data” for advertisers (who then personalize the ads you see), and for political candidates, who can target you with persuasive messages. In the 2016 U.S. presidential campaign, “both sides were certainly using big data . . . to win over voters,” says researcher Michal Kosinski (Zakaria, 2017).

By exploring such questions, Big Five research has sustained trait psychology and renewed appreciation for the importance of personality. (To describe your personality, try the brief self-assessment in [FIGURE 14.4](#).) Traits matter. In the next section, we will see that situations matter, too.

How Do You Describe Yourself?

Describe yourself as you generally are now, not as you wish to be in the future. Describe yourself as you honestly see yourself, in relation to other people you know of the same sex and roughly the same age. Use the scale below to enter a number for each statement. Then, use the scoring guide at the bottom to see where you fall on the spectrum for each of the Big Five traits.

1	2	3	4	5
Very Inaccurate	Moderately Inaccurate	Neither Accurate Nor Inaccurate	Moderately Accurate	Very Accurate

- ___ Am the life of the party
- ___ Sympathize with others' feelings
- ___ Get stressed out easily
- ___ Am always prepared
- ___ Am full of ideas
- ___ Start conversations
- ___ Take time out for others
- ___ Follow a schedule
- ___ Worry about things
- ___ Have a vivid imagination

SCORING GUIDE SORTED BY BIG FIVE PERSONALITY TRAITS

Conscientiousness: statements 4, 8
 Agreeableness: statements 2, 7
 Neuroticism: statements 3, 9
 Openness: statements 5, 10
 Extraversion: statements 1, 6

How to score:
 Separate your responses by each Big Five personality trait, as noted at left, and divide by two to obtain your score for each trait. So, for example, for the "Agreeableness" trait let's say you scored 3 for statement 2 ("Sympathize with others' feelings") and 4 for statement 7 ("Take time out for others"). That means on a scale from 1 to 5, your overall score for the "Agreeableness" trait is $3 + 4 = 7 \div 2 = 3.5$.

Scale data from Goldberg, L. R. (1992). The development of markers for the Big-Five factor structure. *Psychological Assessment*, 4, 26–42.

FIGURE 14.4 The Big Five self-assessment

RETRIEVAL PRACTICE

RP-9 What are the *Big Five* personality factors, and why are they scientifically useful?

ANSWER: The Big Five personality factors are conscientiousness, agreeableness, neuroticism (emotional stability vs. instability), openness, and extraversion: CANOE. These factors may be objectively measured, they are relatively stable over the life span, and they apply to all cultures in which they have been studied.

For a review of the Big Five, engage online with **Concept Practice: The Big Five Personality Traits**.

Evaluating Trait Theories

LOQ 14-17 Does research support the consistency of personality traits over time and across situations?

Are our personality traits stable and enduring? Or does our behavior depend on where and with whom we find ourselves? In some ways, our personality seems stable. Cheerful, friendly children tend to become cheerful, friendly adults. At a college reunion, I [DM] was amazed to find that my jovial former classmates were still jovial, the shy ones still shy, the happy-seeming people still smiling and laughing *50 years later*. But it's also true that a fun-loving jokester can suddenly turn serious and respectful at a job interview. New situations and major life events can shift the personality traits we express. Becoming unemployed, for example, may make us less agreeable and open-minded (Boyce et al., 2015).

“There is as much difference between us and ourselves, as between us and others.”

Michel de Montaigne, *Essays*, 1588

THE PERSON-SITUATION CONTROVERSY Our behavior is influenced by the interaction of our inner disposition with our environment. Still, the question lingers: Which is more important? When we explore this *person-situation controversy*, we look for genuine personality traits that persist over time *and* across situations. Are some people dependably conscientious and others unreliable, some cheerful and others dour, some friendly and outgoing and others shy? If we are to consider friendliness a trait, friendly people must act friendly at different times and places. Do they?

Roughly speaking, the temporary, external influences on behavior are the focus of *social psychology* ([Chapter 13](#)), and the enduring, inner influences are the focus of *personality psychology*. In actuality, behavior always depends on the interaction of persons with situations.

In earlier chapters, we considered research that has followed lives through

time. We noted that some scholars (especially those who study infants) are impressed with personality change; others are struck by personality stability during adulthood. As [FIGURE 14.5](#) illustrates, data from 152 long-term (*longitudinal*) studies reveal that personality trait scores are positively correlated with scores obtained seven years later, and that as people grow older, their personality stabilizes. Interests may change—the avid tropical-fish collector may become an avid gardener. Careers may change—the determined salesperson may become a determined social worker. Relationships may change—the hostile spouse may start over with a new partner. But most people recognize just who they are, as Robert McCrae and Paul Costa noted (1994), “and it is well that they do. A person’s recognition of the inevitability of his or her one and only personality is . . . the culminating wisdom of a lifetime.”

FIGURE 14.5 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Roberts & DelVecchio, 2000

FIGURE 14.5 Personality stability

With age, personality traits become more stable, as reflected in the stronger correlation of trait scores with follow-up scores 7 years later.

So most people—including most psychologists—would probably presume the stability of personality traits. Moreover, our traits are socially significant. They influence our health, our thinking, and our job choices and performance (Hogan, 1998; Jackson et al., 2012; Sutin et al., 2011). Studies that follow lives through time show that personality traits rival socioeconomic status and cognitive ability as predictors of mortality, divorce, and occupational attainment (Roberts et al., 2007).

Change and consistency can coexist. If all people were to become somewhat less shy with age, there would be personality change, but also relative stability and predictability.

Although our personality *traits* may be both stable and potent, the consistency of our specific *behaviors* from one situation to the next is another matter. What relationship would you expect to find between being conscientious in one situation (say, showing up for class on time) and being conscientious in another (say, avoiding unhealthy foods)? If you've noticed how outgoing you are in some situations and how reserved you are in others, perhaps you said, "Very little." That's what researchers have found—only a small correlation (Mischel, 1968; Sherman et al., 2015). This inconsistency in behaviors also makes personality test scores weak predictors of behaviors. People's scores on an extraversion test, for example, do not neatly predict how sociable they actually will be on any given occasion.

If we remember such results, we will be more cautious about labeling and pigeonholing individuals (Mischel, 1968). Years in advance, science can tell us the phase of the Moon for any given date. A day in advance, meteorologists can often predict the weather. But we are much further from being able to predict how *you* will feel and act tomorrow.

However, people's *average* outgoingness, happiness, or carelessness over many situations is predictable (Epstein, 1983a,b). People who know someone well, therefore, generally agree when rating that person's shyness or agreeableness (Jackson et al., 2015; Kenrick & Funder, 1988). By collecting snippets of people's daily experience via body-worn recording devices, Matthias Mehl and his colleagues (2006) confirmed that extraverts really do talk more. (I [DM] have repeatedly vowed to cut back on my jabbering and joking during my noontime pickup basketball games with friends. Alas, moments later, the irrepressible chatterbox inevitably reoccupies my body. And I [ND] have a similar experience each time I try to stay quiet in taxis. Somehow, I always end up chatting with the driver!) As our best friends can verify, we do have persistent (genetically influenced) personality traits. And our personality traits get expressed in our

my hair over time

© Mitra Farmand, www.fuffernutter.com

It's not just personality that stabilizes with age.

- *music preferences*. Your playlist reveals something of your personality. Classical, jazz, blues, and folk music lovers tend to be open to experience and verbally intelligent. Extraverts tend to prefer upbeat and energetic music. Country, pop, and religious music lovers tend to be cheerful, outgoing, and conscientious (Langmeyer et al., 2012; Rentfrow & Gosling, 2003, 2006).
- *written communications*. If you have ever felt you could detect someone's personality from their writing voice, you are right!! What a cool finding!!! ☺ People's writings—even their brief tweets and Facebook posts—often express their extraversion, self-esteem, and agreeableness (Orehek & Human, 2017; Park et al., 2015; Pennebaker, 2011). “Off to meet a friend. Woohoo!!!,” posted one Facebook user who had scored high on extraversion (Kern et al., 2014). Extraverts also use more adjectives.
- *online and personal spaces*. Are online profiles, websites, and avatars also a canvas for self-expression? Or are they an opportunity for people to present themselves in false or misleading ways? It's more the former (Back et al., 2010; Gosling et al., 2007; Marcus et al., 2006). People who seemed most likable on their Facebook or Twitter pages also seemed most likable in person (Qiu et al., 2012; Weisbuch et al., 2009). Even mere photos, with their

associated clothes, expressions, and postures, can give clues to personality (Naumann et al., 2009). Our living and working spaces also help us express our identity. They all offer clues to our extraversion, agreeableness, conscientiousness, and openness (Back et al., 2010; Fong & Mar, 2015; Gosling, 2008).

Victoria Roberts The New Yorker Collection/
The Cartoon Bank

In unfamiliar, formal situations—perhaps as a guest in the home of a person from another culture—our traits remain hidden as we carefully attend to social cues. In familiar, informal situations—just hanging out with friends—we feel less constrained, allowing our traits to emerge (Buss, 1989). In these informal situations, our expressive styles—our animation, manner of speaking, and gestures—are impressively consistent. Viewing “thin slices” of someone’s behavior—such as seeing a photo for a mere fraction of a second, or seeing several 2-second video clips of a teacher in action—can tell us a lot about the person’s basic personality traits (Ambady, 2010; Tackett et al., 2016).

Some people are naturally expressive (and therefore talented at pantomime and charades); others are less expressive (and therefore better poker players). To evaluate people’s voluntary control over their expressiveness, Bella DePaulo and her colleagues (1992) asked people to *act* as expressive or inhibited as possible while stating opinions. Their remarkable findings: Inexpressive people, even when feigning expressiveness, were less expressive than expressive people acting naturally. Similarly, expressive

people, even when trying to seem inhibited, were less inhibited than inexpressive people acting naturally. It's hard to be someone you're not, or not to be who you are.

Gary Houlder/Getty Images

Room with a cue

Even at “zero acquaintance,” people can catch a glimpse of others’ personality from looking at their online and personal spaces. So, what’s your read on this person?

To sum up, we can say that at any moment the immediate situation powerfully influences a person’s behavior. Social psychologists have learned that this is especially so when a “strong situation” makes clear demands (Cooper & Withey, 2009). We can better predict drivers’ behavior at traffic lights from knowing the color of the lights than from knowing the drivers’ personalities. Thus, professors may perceive certain students as subdued (based on their classroom behavior), but friends may perceive them as pretty wild (based on their party behavior). Averaging our behavior across many occasions does, however, reveal distinct personality traits. Traits exist. We differ. And our differences matter.

For a demonstration of trait research, view the 8-minute **Video: Trait Theories of Personality**.

RETRIEVAL PRACTICE

RP-10 How well do personality test scores predict our behavior? Explain.

ANSWER: Our scores on personality tests predict our *average* behavior across many situations much better than they predict our specific behavior in any given situation.

Maslow's hierarchy of needs proposes that we must satisfy basic physiological and safety needs before we seek ultimate psychological needs, such as self-actualization. Maslow based his ideas on

- Freudian theory.
- his experiences with patients.
- a series of laboratory experiments.
- his study of healthy, creative people.

How might Rogers explain how environment influences the development of a criminal?

The total acceptance Rogers advocated as part of a growth-promoting environment is called _____

_____.

_____ theories of personality focus on describing characteristic behavior patterns, such as agreeableness or extraversion.

One famous personality inventory is the

- a. Extraversion–Introversion Scale.
- b. Person–Situation Inventory.
- c. MMPI.
- d. Rorschach.

Which of the following is NOT one of the Big Five personality factors?

- a. Conscientiousness
- b. Anxiety
- c. Extraversion
- d. Agreeableness

Our scores on personality tests best predict

- a. our behavior on a specific occasion.
- b. our average behavior across many situations.
- c. behavior involving a single trait, such as conscientiousness.
- d. behavior that depends on the situation or context.

Social-Cognitive Theories and the Self

Social-Cognitive Theories

LOQ 14-18 How do social-cognitive theorists view personality development, and how do they explore behavior?

The [social-cognitive perspective](#) on personality that Albert Bandura (1986, 2006, 2008) proposed emphasizes the interaction of our traits with our situations. Much as nature and nurture always work together, so do individuals and their situations.

social-cognitive perspective views behavior as influenced by the interaction between people's traits (including their thinking) and their social context.

Social-cognitive theorists believe we learn many of our behaviors either through conditioning or by observing and imitating others. (That's the "social" part.) They also emphasize the importance of mental processes: What we *think* about a situation affects our resulting behavior. (That's the "cognitive" part.) Instead of focusing solely on how our environment *controls* us (behaviorism), social-cognitive theorists focus on how we and our environment *interact*: How do we interpret and respond to external events? How do our schemas, our memories, and our expectations influence our behavior patterns?

Reciprocal Influences

Bandura (1986, 2006) views the person-environment interaction as [reciprocal determinism](#). "Behavior, internal personal factors, and environmental influences," he said, "all operate as interlocking determinants of each other"

(**FIGURE 14.6**). We can see this interaction in people's relationships. For example, Rosa's past romantic experience (her behaviors) influence her romantic attitudes (internal factor), which affect how she now responds to Ryan (environmental factor).

reciprocal determinism the interacting influences of behavior, internal cognition, and environment.

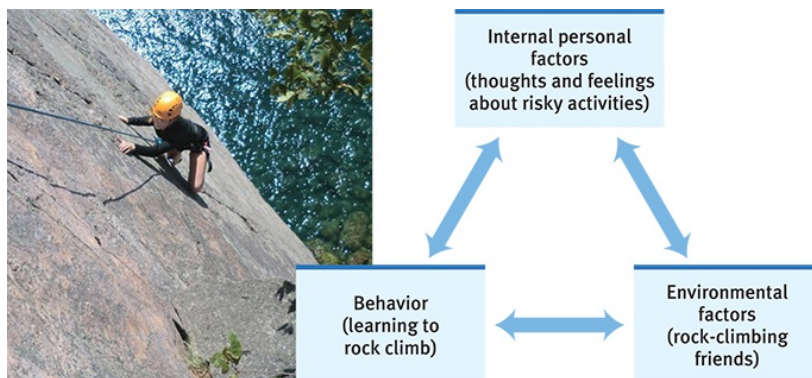

FIGURE 14.6 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Courtesy of Joslyn Brugh

FIGURE 14.6 Reciprocal determinism

Consider three specific ways in which individuals and environments interact:

Different people choose different environments. The schools we attend, the reading we do, the movies we watch, the music we listen to, the friends we associate with—all are part of an environment we have chosen, based partly on our disposition (Funder, 2009; Ickes et al., 1997). People with inflated self-esteem choose to post frequent selfies in online environments, where they can receive the public attention and praise they crave. This leads to even greater self-love (Halpern et al., 2016). We choose our environment and it then shapes us.

Our personalities shape how we interpret and react to events. Anxious people tend to attend and react strongly to relationship threats (Campbell & Marshall, 2011). If we perceive the world as threatening, we will watch for threats and be prepared to defend ourselves.

Our personalities help create situations to which we react. How we view

and treat people influences how they then treat us. If we expect that others will not like us, our bragging and other efforts to seek their approval might cause them to reject us (Scopelliti et al., 2015).

In addition to the interaction of internal personal factors, the environment, and our behaviors, we also experience *gene-environment interaction* ([Chapter 4](#)). Our genetically influenced traits evoke certain responses from others, which may nudge us in one direction or another. In one classic study, those with the interacting factors of (1) having a specific gene associated with aggression plus (2) being raised in a difficult environment were most likely to demonstrate adult antisocial behavior (Caspi et al., 2002).

In such ways, we are both the products and the architects of our environments: *Behavior emerges from the interplay of external and internal influences*. Boiling water turns an egg hard and a potato soft. A threatening environment turns one person into a hero, another into a scoundrel. Extraverts enjoy greater well-being in an extraverted culture than in an introverted one (Fulmer et al., 2010). *At every moment*, our behavior is influenced by our biology, our social and cultural experiences, and our cognition and dispositions ([FIGURE 14.7](#)).

_____.

ANSWER: social-cognitive; reciprocal determinism

Assessing Behavior in Situations

To predict behavior, social-cognitive psychologists often observe behavior in realistic situations. One ambitious example was the U.S. Army's World War II strategy for assessing candidates for spy missions. Rather than using paper-and-pencil tests, Army psychologists subjected the candidates to simulated undercover conditions. They tested their ability to handle stress, solve problems, maintain leadership, and withstand intense interrogation without blowing their cover. Although time-consuming and expensive, this assessment of behavior in a realistic situation helped predict later success on actual spy missions (OSS Assessment Staff, 1948).

Military and educational organizations and many Fortune 500 companies have adopted assessment center strategies (Bray & Byham, 1991, 1997; Eurich et al., 2009). AT&T has observed prospective managers doing simulated managerial work. Many colleges assess nursing students' potential by observing their clinical work, and they assess potential faculty members' teaching abilities by observing them teach. Most American cities with populations of 50,000 or more have used assessment centers in evaluating police officers and firefighters (Lowry, 1997).

Gustavo Caballero/Getty Images

If you can't stand the heat. . .

On the Food Network's *Chopped*, contestants are pitted against one another in stressful situations. The entertaining episodes illustrate a valid point: A chef's behavior in such job-relevant situations can help predict job performance.

These procedures exploit the principle that the best means of predicting behavior is neither a personality test nor an interviewer's intuition. Rather, *the best predictor of future behavior is the person's past behavior patterns in similar situations* (Lyons et al., 2011; Mischel, 1981; Schmidt & Hunter, 1998). As long as the situation and the person remain much the same, the best predictor of future job performance is past job performance; the best predictor of future grades is past grades; the best predictor of future aggressiveness is past aggressiveness. If you can't check the person's past behavior, the next best thing is to create an assessment situation that simulates the task so you can see how the person handles it (Lievens et al., 2009; Meriac et al., 2008).

"What's past is prologue."

William Shakespeare, *The Tempest*, 1611

Evaluating Social-Cognitive Theories

LOQ 14-19 What criticisms have social-cognitive theorists faced?

Social-cognitive theories of personality sensitize researchers to how situations affect, and are affected by, individuals. More than other personality theories (see [TABLE 14.4](#)), they build from psychological research on learning and cognition.

TABLE 14.4
Comparing the Major Personality Theories

Personality Theory	Key Proponents	Assumptions	View of Personality	A
<i>Psychoanalytic</i>	Freud	Emotional disorders spring from unconscious dynamics, such as unresolved sexual and other childhood conflicts, and fixation at various developmental stages. Defense mechanisms fend off anxiety.	Personality consists of pleasure-seeking impulses (the id), a reality-oriented executive (the ego), and an internalized set of ideals (the superego).	Fr as pr dr
<i>Psychodynamic</i>	Adler, Horney, Jung	The unconscious and conscious minds interact.	The dynamic interplay of conscious and unconscious	Pr te se

			behavior in one situation is best predicted by considering our past behavior in similar situations.	
--	--	--	---	--

Critics charge that social-cognitive theories focus so much on the situation that they fail to appreciate the person's inner traits. Where is the person in this view of personality, ask the dissenters, and where are human emotions? True, the situation does guide our behavior. But, say the critics, in many instances our unconscious motives, our emotions, and our pervasive traits shine through. Personality traits have been shown to predict behavior at work, in love, and at play. Our biologically influenced traits really do matter. Consider Percy Ray Pridgen and Charles Gill. Each faced the same situation: They had jointly won a \$90 million lottery jackpot (Harriston, 1993). When Pridgen learned of the winning numbers, he began trembling uncontrollably, huddled with a friend behind a bathroom door while confirming the win, and then sobbed. When Gill heard the news, he told his wife and went to sleep.

RETRIEVAL PRACTICE

RP-12 What is the best way to predict a person's future behavior?

ANSWER: Examine the person's past behavior patterns in similar situations.

To review the perspectives and methods discussed in this chapter, engage online with **Concept Practice: Comparing Personality Theories**.

Exploring the Self

LOQ 14-20 Why has psychology generated so much research on the self? How important is self-esteem to our well-being?

Our personality feeds our sense of self. Asked to consider “Who I am,” people draw on their distinctive and enduring ways of thinking, feeling, and acting. Psychology’s concern with our sense of self dates back at least to William James, who devoted more than 100 pages of his 1890 *Principles of Psychology* to the topic. By 1943, Gordon Allport lamented that the self had become “lost to view.” Although humanistic psychology’s later emphasis on the self did not instigate much scientific research, it did help renew the concept of self and keep it alive. Now, more than a century after James, the self is one of Western psychology’s most vigorously researched topics. Every year, new studies galore appear on self-esteem, self-disclosure, self-awareness, self-schemas, self-monitoring, and more. Even neuroscientists have searched for the self, by identifying a central frontal lobe region that activates when people respond to self-reflective questions about their traits and dispositions (Damasio, 2010; Mitchell, 2009; Pauly et al., 2013). The [self](#), as organizer of our thoughts, feelings, and actions, occupies the center of personality.

self in contemporary psychology, assumed to be the center of personality, the organizer of our thoughts, feelings, and actions.

One example of thinking about self is the concept of *possible selves* (Markus & Nurius, 1986; Rathbone et al., 2016). Your possible selves include your visions of the self you dream of becoming—the rich self, the successful self, the loved and admired self. Your possible selves also include the self you fear becoming—the unemployed self, the academically failed self, the lonely and unpopular self. Possible selves motivate us to lay out specific goals that direct our energy effectively and efficiently (Landau et al., 2014). Middle school students whose families struggle financially are more likely to earn high grades if they have a clear vision of themselves succeeding in school (Duckworth et al., 2013). Dreams do often give birth to achievements.

“The first step to better times is to imagine them.”

Chinese fortune cookie

Our self-focused perspective may motivate us, but it can also lead us to presume too readily that others are noticing and evaluating us. Thomas Gilovich (1996) demonstrated this [spotlight effect](#) by having Cornell University students don T-shirts featuring soft-rock star Barry Manilow before entering a room with other students. Feeling self-conscious, the T-shirt wearers guessed that nearly half their peers would take note of the shirt as they walked in. In reality, only 23 percent did. The point to remember: *We stand out less than we imagine*, even with dorky clothes and bad hair, and even after a blunder like setting off a library alarm (Gilovich & Savitsky, 1999; Savitsky et al., 2001).

spotlight effect overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us).

To turn down the spotlight's brightness, we can use two strategies. The first is simply to know and remember the spotlight effect. Public speakers perform better if they understand that their natural nervousness is hardly noticeable (Savitsky & Gilovich, 2003). The second is to take the audience's perspective. When we imagine audience members empathizing with our situation, we tend to expect we will not be judged as harshly (Epley et al., 2002).

Mirror/Mirrorpix/Alamy

The Benefits of Self-Esteem

Self-esteem—our feelings of high or low self-worth—matters. So does **self-efficacy**, our sense of competence on a task (Bandura, 1977). (A student might feel high self-efficacy in a math course yet low overall self-esteem.) People who feel good about themselves (who strongly agree with self-affirming questionnaire statements, such as “I am fun to be with”) have fewer sleepless nights. They succumb less easily to pressures to conform. They make more positive Facebook posts, causing others to like them more (Forest & Wood, 2012). They are more persistent at difficult tasks. They feel less shy, anxious, and lonely, and are just plain happier (Greenberg, 2008; Orth & Robins, 2014; Swann et al., 2007). If feeling bad, they think they deserve better and thus make more effort to repair their mood (Wood et al., 2009). Our self-esteem grows from venturesome experiences and achievement, and therefore changes as we age (Hutteman et al., 2015). In one study of nearly 1 million people across 48 nations, self-esteem increased from adolescence to middle adulthood (Bleidorn et al., 2016).

self-esteem one's feelings of high or low self-worth.

self-efficacy one's sense of competence and effectiveness.

But is high self-esteem the horse or the cart? Is it really “the armor that protects kids” from life’s problems (McKay, 2000)? Some psychologists have their doubts (Baumeister, 2006; Dawes, 1994; Leary, 1999; Seligman, 1994, 2002). Children’s academic self-efficacy—their confidence that they can do well in a subject—predicts school achievement. But general self-image does not (Marsh & Craven, 2006; Swann et al., 2007; Trautwein et al., 2006). Maybe self-esteem simply reflects reality. Maybe it’s a side effect of meeting challenges and surmounting difficulties. Maybe self-esteem is a gauge that reports the state of our relationships with others (Reitz et al., 2016). If so, isn’t pushing the gauge artificially higher with empty compliments much like forcing a car’s low fuel gauge to display “full”?

If feeling good *follows* doing well, then giving praise in the absence of good performance may actually harm people. After receiving weekly self-esteem-boosting messages, struggling students earned *lower*-than-expected grades (Forsyth et al., 2007). Other research showed that giving people random rewards hurt their productivity. Martin Seligman (2012) reported that “when good things occurred that weren’t earned, like nickels coming out of slot machines, it did not increase people’s well-being. It produced helplessness. People gave up and became passive.”

“When kids increase in self-control, their grades go up later. But when kids increase their self-esteem, there is no effect on their grades.”

Angela Duckworth, *In Character* interview, 2009

There is, however, an important *effect* of low self-esteem. When researchers temporarily deflated people’s self-image (by telling them they did poorly on an aptitude test or by disparaging their personality), those participants became more likely to disparage others or to express heightened racial prejudice (van Dijk et al., 2011; vanDellen et al., 2011; Ybarra, 1999). Self-image threat even increases unconscious racial bias (Allen & Sherman,

2011). Those who are negative about themselves have also tended to be oversensitive and judgmental (Baumgardner et al., 1989; Pelham, 1993). Self-esteem threats also lead people to spend more time with their online profiles—safe havens in which to rebuild their self-worth (Toma & Hancock, 2013). Such findings are consistent with humanistic psychology’s ideas about the benefits of a healthy self-image. Accept yourself and you’ll find it easier to accept others. Disparage yourself and you will be prone to the floccinaucinihilipilification¹ of others. Said more simply, some “love their neighbors as themselves”; others loathe their neighbors as themselves. People who are down on themselves tend to be down on others.

The Costs of Self-Esteem

LOQ 14-21 How do excessive optimism, blindness to one’s own incompetence, and self-serving bias reveal the costs of self-esteem, and how do defensive and secure self-esteem differ?

EXCESSIVE OPTIMISM Positive thinking in the face of adversity can pay dividends, but so, too, can a dash of realism (Schneider, 2001). Realistic anxiety over possible future failures can fuel energetic efforts to avoid the dreaded fate (Goodhart, 1986; Norem, 2001; Showers, 1992). Concerned about failing an upcoming exam, students may study thoroughly and outperform their equally able but more confident peers. Asian-American students have expressed somewhat greater pessimism than their European-

American counterparts, which may help explain their often impressive academic achievements (Chang, 2001). Success requires enough optimism to provide hope and enough pessimism to prevent complacency. We want our airline pilots to be mindful of worst-possible outcomes.

Excessive optimism can blind us to real risks (Tenney et al., 2015). More than 1000 studies have shown how our natural positive thinking bias can promote “an unrealistic optimism about future life events” (Shepperd et al., 2015; Weinstein, 1980). When 56 percent of twelfth graders believed they would earn a graduate degree—though only 9 percent were likely to do so—that was unrealistic optimism (Reynolds et al., 2006). When most students perceived themselves as more likely than their classmates to get a high-paying job and own a nice home, and less likely to have a heart attack or get cancer, that, too, was unrealistic optimism (Waters et al., 2011). If overconfident of our ability to control an impulse such as the urge to smoke, we are more likely to expose ourselves to temptations—and to fail (Nordgren et al., 2009). Blind optimism can be self-defeating, as we can see in those who optimistically deny the addictive toxicity of smoking, venture into ill-fated relationships, and invest money in risky schemes.

Our natural positive thinking bias does seem to vanish, however, when we are bracing ourselves for feedback, such as exam results (Carroll et al., 2006). In one analysis of 71 studies, most people shifted their expectations downward shortly before the moment of truth (Sweeny & Krizan, 2013). Positive illusions also vanish after a traumatic personal experience—as they did for victims of a catastrophic California earthquake, who had to give up their illusions of being less vulnerable than others to earthquakes (Helweg-Larsen, 1999).

BLINDNESS TO ONE’S OWN INCOMPETENCE Ironically, people often are most overconfident when most incompetent. That, said Justin Kruger and David Dunning (1999), is because it often takes competence to recognize competence. They found that most students scoring at the low end of grammar and logic tests believed they had scored in the top half. If you do not know what is logical, you may be unaware of your illogic. This “ignorance of one’s own incompetence” phenomenon—now called the *Dunning-Kruger effect*—can produce overconfidence among political leaders. It also has a parallel among those of us with hearing loss, as I [DM] can confirm. Because we are unaware of what we don’t hear, we may

overestimate our hearing. If I fail to hear my friend calling my name, the friend notices my inattention. But for me it's a nonevent. I hear what I hear—which, to me, seems pretty normal.

The difficulty in recognizing one's own incompetence helps explain why so many low-scoring students are dumbfounded after blowing an exam. If you don't know all the Scrabble word possibilities you've overlooked, you may feel pretty smart—until they are pointed out. Our ignorance of what we don't know sustains our self-confidence, leading us to make the same mistakes (Williams et al., 2013).

To judge one's competence and predict one's future performance, it pays to invite others' assessments (Dunning, 2006; Grossmann & Kross, 2014). Based on studies in which both individuals and their acquaintances predict their future, we can hazard some advice: Ask your peers for their candid prediction. If you're in love and want to predict whether it will last, don't listen to your heart—ask your roommate.

SELF-SERVING BIAS Imagine dashing to class, hoping not to miss the first few minutes. But you arrive five minutes late, huffing and puffing. As you sink into your seat, what sorts of thoughts go through your mind? Do you go through a negative door, thinking “I hate myself” and “I’m a loser”? Or do you go through a positive door, telling yourself “At least I made it to class” and “I really tried to get here on time”?

Personality psychologists have found that most people choose the second door, which leads to positive self-thoughts. We have a good reputation with ourselves. We show a [self-serving bias](#)—a readiness to perceive ourselves favorably (Myers, 2010). Consider:

self-serving bias a readiness to perceive oneself favorably.

People accept more responsibility for good deeds than for bad, and for successes than for failures. Athletes often privately credit their victories to their own prowess, and their losses to bad breaks, lousy officiating, or the other team's exceptional performance. Most students who receive poor exam grades criticize the exam or the instructor, not themselves. Drivers filling out insurance forms have explained their accidents in such words as “A

pedestrian hit me and went under my car.” The question “What have I done to deserve this?” is one we usually ask of our troubles, not our successes. Although a self-serving bias can lead us to avoid uncomfortable truths, it can also motivate us to approach difficult tasks with confidence instead of despair (Tomaka et al., 1992; von Hippel & Trivers, 2011).

“I never blame myself when I’m not hitting. I just blame the bat and if it keeps up, I change bats.”

Baseball great Yogi Berra, (1925–2015)

Most people see themselves as better than average. Compared with most other people, how moral are you? How easy to get along with? Where would you rank yourself, from the 1st to the 99th percentile? Most people put themselves well above the 50th percentile. This better-than-average effect appears for nearly any subjectively assessed and socially desirable behavior. Some examples:

DOONESBURY

Universal Press Syndicate

- In U.S. surveys, most business executives say they are more ethical than their average counterpart. In several studies, 90 percent of business managers and more than 90 percent of college professors also rated their performance as superior to that of their average peer.
- In Australia, 86 percent of people rate their job performance as

above average, and only 1 percent as below average.

- In the U.S. National Survey of Families and Households, 49 percent of men said they provided half or more of the child care, though only 31 percent of their wives or partners saw things that way (Galinsky et al., 2008).

Self-serving bias reflects both an overestimation of the self and a desire to maintain a positive self-view (Brown, 2012; Epley & Dunning, 2000). This motivation to see ourselves positively is weaker in Asia, where people tend to value modesty (Church et al., 2014; Falk et al., 2009). Yet self-serving biases have been observed worldwide: In every one of 53 countries surveyed, people expressed self-esteem above the midpoint of the most widely used scale (Schmitt & Allik, 2005). The world, it seems, is Garrison Keillor's Lake Wobegon writ large—a place where “all the women are strong, all the men are good-looking, and all the children are above average.”

“If you are like most people, then like most people, you don't know you're like most people. Science has given us a lot of facts about the average person, and one of the most reliable of these facts is the average person doesn't see herself as average.”

Daniel Gilbert, *Stumbling on Happiness*, 2006

Finding their self-esteem threatened, people with large egos may react violently. Researchers Brad Bushman and Roy Baumeister (1998; Bushman et al., 2009) had undergraduate volunteers write a brief essay, in response to which another supposed student gave them either praise (“Great essay!”) or stinging criticism (“One of the worst essays I have read!”). The essay writers were then allowed to lash out at their evaluators by blasting them with

unpleasant noise. Can you anticipate the result? After criticism, those with inflated self-esteem were “exceptionally aggressive.” They delivered a three times greater noise blast than did those with normal self-esteem. Over 80 follow-up studies have replicated the dangerous effect of [narcissism](#) (excessive self-love and self-focus) on aggression (Rasmussen, 2016). Researchers have concluded that “conceited, self-important individuals turn nasty toward those who puncture their bubbles of self-love” (Baumeister, 2001).

narcissism excessive self-love and self-absorption.

“The [self-]portraits that we actually believe, when we are given freedom to voice them, are dramatically more positive than reality can sustain.”

Shelley Taylor, *Positive Illusions*, 1989

After tracking self-importance across several decades, psychologist Jean Twenge (2006; Twenge & Foster, 2010) reported that what she called *Generation Me*—born in the 1980s and 1990s—expressed more narcissism (by agreeing more often with statements such as, “If I ruled the world, it would be a better place,” or “I think I am a special person”). Why does a rise in narcissism matter? Narcissists tend to be materialistic, desire fame, have inflated expectations, hook up more often without commitment, and gamble and cheat more—all of which have been increasing as narcissism has increased. Narcissistic people (more often men) forgive others less, take a game-playing approach to their romantic relationships, and engage in sexually forceful behavior (Blinkhorn et al., 2015; Bushman et al., 2003; Grijalva et al., 2015). They crave adulation, are active on social media, and often become enraged when criticized (Geukes et al., 2016; Krizan & Johar, 2015; McCain & Campbell, 2017). Many had parents who told them they were superior to others (Brummelman et al., 2015). They typically make good first impressions, which wane over time as their arrogance and bragging gets old (Czarna et al., 2016; Leckelt et al., 2015). Reality television stars are especially narcissistic (Rubinstein, 2016; Young & Pinsky, 2006).

“The enthusiastic claims of the self-esteem movement mostly range from fantasy to hogwash. The effects of self-esteem are small, limited, and not all good.”

Roy Baumeister (1996)

Despite the demonstrated perils of pride, many people object that the idea of self-serving bias overlooks those who feel worthless and unlovable. If self-serving bias prevails, why do so many people disparage themselves? For four reasons: (1) Sometimes self-directed put-downs are *subtly strategic*—they elicit reassuring strokes. Saying “No one likes me” may at least elicit “But not everyone has met you!” (2) Other times, such as before a game or an exam, self-disparaging comments *prepare us for possible failure*. The coach who extols the superior strength of the upcoming opponent makes a loss understandable, a victory noteworthy. (3) A self-disparaging “How could I have been so stupid!” also helps us *learn from our mistakes*. (4) Self-disparagement frequently *pertains to one’s old self*. Asked to remember their really bad behaviors, people recall things from long ago; good behaviors more easily come to mind from their recent past (Escobedo & Adolphs, 2010). Even when they have not changed, people are much more critical of their distant past selves than of their current selves (Wilson & Ross, 2001). “At 18, I was a jerk; today I’m more sensitive.” In their own eyes, chumps yesterday, champs today.

Even so, all of us some of the time (and some of us much of the time) do feel inferior. This is especially true when we compare ourselves with those who are a step or two higher on the ladder of status, looks, income, or ability. Olympians who win silver medals, barely missing gold, show greater sadness on the awards podium compared with the bronze medal winners (Medvec et al., 1995). The deeper and more frequently we have such feelings, the more unhappy or even depressed we become. But for most people, thinking has a naturally positive bias.

“If you compare yourself with others, you may become vain and bitter; for always there will be greater and lesser persons than yourself.”

Max Ehrmann, “Desiderata,” 1927

While recognizing the dark side of excessive self-esteem, some researchers identify two types of self-esteem—defensive and secure (Kernis, 2003; Lambird & Mann, 2006; Ryan & Deci, 2004). *Defensive self-esteem* is fragile. It focuses on sustaining itself, which makes failure and criticism feel threatening. Defensive people may respond to such perceived threats with anger or aggression (Crocker & Park, 2004; Donnellan et al., 2005).

Secure self-esteem is less fragile, because it is less contingent on external evaluations. To feel accepted for who we are, and not for our looks, wealth, or acclaim, relieves pressures to succeed and enables us to focus beyond ourselves. By losing ourselves in relationships and purposes larger than ourselves, we may achieve a more secure self-esteem, satisfying relationships, and greater quality of life (Crocker & Park, 2004). Authentic pride, rooted in actual achievement, supports self-confidence and leadership (Tracy et al., 2009; Weidman et al., 2016; Williams & DeSteno, 2009).

“True humility is not thinking less of yourself; it is thinking of yourself less.”

C. S. Lewis, *Mere Christianity*, 1952

RETRIEVAL PRACTICE

RP-13 What are the positive and negative effects of high self-esteem?

ANSWER: People who feel confident in their abilities are often happier, have greater motivation, and are less susceptible to depression. Inflated self-esteem can lead to self-serving bias, greater aggression, and narcissism.

RP-14 The tendency to accept responsibility for success and blame circumstances or bad luck for failure is called

_____ - _____.

ANSWER: self-serving bias.

RP-15 _____ (Secure/Defensive) self-esteem is linked to angry and aggressive behavior. _____

(Secure/Defensive) self-esteem is a healthier self-image that allows us to focus beyond ourselves and enjoy a higher quality of life.

ANSWER: Defensive; Secure

REVIEW Social-Cognitive Theories and the Self

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

The social-cognitive perspective proposes our personality is shaped by a process called reciprocal determinism, as personal factors, environmental factors, and behaviors interact. An example of an environmental factor is

- a. the presence of books in a home.
- b. a preference for outdoor play.
- c. the ability to read at a fourth-grade level.
- d. the fear of violent action on television.

Critics say that _____ - _____ personality theory is very sensitive to an individual's interactions with particular situations, but that it gives too little attention to the person's enduring traits.

Researchers have found that low self-esteem tends to be linked with life problems. How should this link be interpreted?

- a. Life problems cause low self-esteem.
- b. The answer isn't clear because the link is correlational and does not indicate cause and effect.
- c. Low self-esteem leads to life problems.
- d. Because of the self-serving bias, we must assume that external factors cause low self-esteem.

A fortune cookie advises, "Love yourself and happiness will follow." Is this good advice?

The tendency to overestimate others' attention to and evaluation of our appearance, performance, and blunders is called the

I felt the need to clean my room at home in Indianapolis every Sunday and would spend four to five hours at it. I would take every book out of the bookcase, dust and put it back. At the time I loved doing it. Then I didn't want to do it anymore, but I couldn't stop. The clothes in my closet hung exactly two fingers apart. . . . I made a ritual of touching the wall in my bedroom before I went out because something bad would happen if I didn't do it the right way. I had a constant anxiety about it as a kid, and it made me think for the first time that I might be nuts.

Marc, diagnosed with obsessive-compulsive disorder (from Summers, 1996)

Whenever I get depressed it's because I've lost a sense of self. I can't find reasons to like myself. I think I'm ugly. I think no one likes me. . . . I become grumpy and short-tempered. Nobody wants to be around me. I'm left alone. Being alone confirms that I am ugly and not worth being with. I think I'm responsible for everything that goes wrong.

Greta, diagnosed with depression (from Thorne, 1993, [p. 21](#))

Voices, like the roar of a crowd, came. I felt like Jesus; I was being crucified. It was dark. I just continued to huddle under the blanket, feeling weak, laid bare and defenseless in a cruel world I could no longer understand.

Stuart, diagnosed with schizophrenia (from Emmons et al., 1997)

Now and then, all of us feel, think, or act in ways that may resemble a psychological disorder. We feel anxious, depressed, withdrawn, or suspicious. So it's no wonder that we are drawn to try to understand disturbed psychological states—we sometimes see ourselves in the mental illnesses we study. “To study the abnormal is the best way of understanding the normal,” said William James (1842–1910).

Personally or through friends or family, we may experience the bewilderment and pain of unexplained physical symptoms, irrational fears, or a feeling that life is not worth living. Among American college students, 1 in 3 report an apparent mental health problem (Eisenberg et al., 2011).

Worldwide, more than half a billion people live with mental or behavior disorders (WHO, 2017a). Although their rates and symptoms vary by culture, no known society is free of two terrible disorders—major depressive disorder and schizophrenia (Baumeister & Härter, 2007; Draguns, 1990a,b, 1997). This chapter examines these and other disorders. [Chapter 16](#) considers their *treatment*.

Introduction to Psychological Disorders

Most people would agree that someone who is depressed and stays mostly in bed for three months has a psychological disorder. But what about a grieving father who can't resume his usual social activities three months after his child has died? Where should we draw the line between sadness and depression? Between zany creativity and bizarre irrationality? Between normality and abnormality? Let's start with these questions:

- How should we *define* psychological disorders?
- How should we *understand* disorders? How do underlying biological factors contribute to disorder? How do troubling environments influence our well-being? And how do these effects of nature and nurture interact?
- How should we *classify* psychological disorders? And can we do so in a way that allows us to help people without stigmatizing or labeling them?
- What do we know about *rates* of psychological disorders? How many people have them? Who is vulnerable, and when?

“Who in the rainbow can draw the line where the violet tint ends and the orange tint begins? Distinctly we see the difference of the colors, but where exactly does the one first blendingly enter into the other? So with sanity and insanity.”

Herman Melville, *Billy Budd, Sailor*, 1924

Defining Psychological Disorders

LOQ **LEARNING OBJECTIVE QUESTION** **15-1** How should we draw the line between normality and disorder?

A **psychological disorder** is a syndrome (collection of symptoms) marked by a “clinically significant disturbance in an individual’s cognition, emotion

regulation, or behavior” (American Psychiatric Association, 2013). Such thoughts, emotions, or behaviors are *dysfunctional* or *maladaptive*—they interfere with normal day-to-day life. Believing your home must be thoroughly cleaned every weekend is not a disorder. But if cleaning rituals interfere with work and leisure, as Marc’s uncontrollable rituals did, they may be signs of a disorder. Occasional sad moods that persist and become disabling may likewise signal a psychological disorder.

psychological disorder a syndrome marked by a clinically significant disturbance in an individual’s cognition, emotion regulation, or behavior.

Francois Dubourdeau/Skydive East Tennessee; Carol Beckwith

Culture and normality

Young American men may plan elaborate invitations for big events, as did this student (above left) who appealed (successfully) to his date for prom. Young men of the West African Wodaabe tribe (above right) traditionally put on decorative makeup and costumes to attract women. Each culture may view the other’s behavior as abnormal.

Distress often accompanies such dysfunction. Marc, Greta, and Stuart were all distressed by their thoughts, emotions, or behaviors.

Over time, definitions of what makes for a “significant disturbance” have varied. From 1952 through December 9, 1973, homosexuality was classified as a psychological disorder. By day’s end on December 10, it was not. The American Psychiatric Association made this change because more and more of its members no longer viewed same-sex attraction as a psychological problem. Such is the power of shifting societal beliefs. (Later research revealed, however, that the *stigma and stresses* that people who are gay, lesbian, transgender, and gender nonconforming often experience can increase the risk of mental health problems [Hatzenbuehler et al., 2009; Meyer, 2003].) In the twenty-first century, other controversies swirl over new

or altered diagnoses in the most recent classification tool for describing disorders.

RETRIEVAL PRACTICE

RP-1 A lawyer is distressed by feeling the need to wash his hands 100 times a day. He has little time to meet with clients, and his colleagues are wondering about his competence. His behavior would probably be labeled disordered, because it is _____, that is, it interferes with his day-to-day life.

ANSWER: dysfunctional or maladaptive

Understanding Psychological Disorders

LOQ 15-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The way we view a problem influences how we try to solve it. In earlier times, people often viewed strange behaviors as evidence of strange forces—the movements of the stars, godlike powers, or evil spirits—at work. Had you lived during the Middle Ages, you might have said “The devil made him do it.” Believing that, you might have approved of a harsh cure that would drive out the evil demon. Thus, people considered “mad” were sometimes caged or given “therapies” such as genital mutilation, beatings, removal of teeth or lengths of intestines, or transfusions of animal blood (Farina, 1982).

Reformers such as Philippe Pinel (1745–1826) in France opposed such brutal treatments. Madness is not demonic possession, he insisted, but a sickness of the mind caused by severe stress and inhumane conditions. Curing the illness, he said, requires *moral treatment*, including boosting patients’ spirits by unchaining them and talking with them. He and others worked to replace brutality with gentleness, isolation with activity, and filth with clean air and sunshine.

John W. Verano

Yesterday's "therapy"

Through the ages, psychologically disordered people have received brutal treatments, including the trephination evident in this Stone Age patient's skull. Drilling skull holes like these may have been an attempt to release evil spirits and cure those with mental disorders. Did this patient survive the "cure"?

In some places, cruel treatments for mental illness—including chaining people to beds or confining them in spaces with wild animals—linger even today. The World Health Organization has launched a reform that aims to transform hospitals worldwide “into patient-friendly and humane places with minimum restraints” (WHO, 2014a).

Dance in a Madhouse, 1917 (litho)/Bellows, George Wesley (1882–1925)/SAN DIEGO MUSEUM OF ART/San Diego Museum of Art, USA/Bridgeman Images

Moral treatment

Under Philippe Pinel's influence, hospitals sometimes sponsored patient dances, often called "lunatic balls," as depicted in this painting by George Bellows (*Dance in a Madhouse*).

The Medical Model

By the 1800s, a medical breakthrough prompted further reforms. Researchers discovered that syphilis infects the brain and distorts the mind. This discovery triggered an eager search for physical causes of other mental disorders, and for treatments that would cure them. Hospitals replaced asylums, and the **medical model** of mental disorders was born. This model is reflected in the terms we still use today. We speak of the mental *health* movement: A mental *illness* (also called a *psychopathology*) needs to be *diagnosed* on the basis of its *symptoms*. It needs to be *treated* through *therapy*, which may include time in a psychiatric *hospital*.

medical model the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*.

The medical perspective has been energized by more recent discoveries that genetically influenced abnormalities in brain structure and biochemistry contribute to many disorders (Insel & Cuthbert, 2015). A growing number of clinical psychologists now work in medical hospitals, where they collaborate with physicians to determine how the mind and body operate together.

The Biopsychosocial Approach

To call psychological disorders “sicknesses” tilts research heavily toward the influence of biology and away from the influence of our personal histories and social and cultural surroundings. But in the study of disorders, as in so many other areas, biological, psychological, and social-cultural influences together weave the fabric of our behaviors, our thoughts, and our feelings. As individuals, we differ in the amount of stress we experience and in the ways we cope with stressors. Cultures also differ in their sources of stress and in their traditional ways of coping. We are physically embodied and socially embedded.

Two disorders—major depressive disorder and schizophrenia—occur worldwide. From Asia to Africa and across the Americas, schizophrenia’s symptoms often include irrationality and incoherent speech. Other disorders tend to be associated with specific cultures. Latin America lays claim to *susto*, a condition marked by severe anxiety, restlessness, and a fear of black magic. In Japanese culture, people may experience *taijin kyofusho*—social anxiety about their appearance, combined with a readiness to blush and a fear of eye contact. The eating disorders anorexia nervosa and bulimia nervosa occur mostly in food-abundant Western cultures. Such disorders may share an underlying dynamic (such as anxiety) while differing in the symptoms (an eating problem or a type of fear) manifested in a particular culture. Even disordered aggression may have varying explanations in different cultures. In Malaysia, *amok* describes a sudden outburst of violent behavior (as in the English phrase “run amok”).

Disorders reflect genetic predispositions and physiological states, inner psychological dynamics, and social and cultural circumstances. The biopsychosocial approach emphasizes that mind and body are inseparable (**FIGURE 15.1**). Negative emotions can contribute to physical illness, and physical abnormalities can likewise contribute to negative emotions. The biopsychosocial approach gave rise to the *vulnerability-stress model*, which argues that individual characteristics combine with environmental stressors to

increase or decrease the likelihood of developing a psychological disorder (Monroe & Simons, 1991; Zuckerman, 1999). Research on [epigenetics](#) (literally, “in addition to genetic”) supports the vulnerability-stress model by showing how our DNA and our environment interact. In one environment, a gene will be *expressed*, but in another, it may lie dormant. For some, that will be the difference between developing a disorder or not developing it.

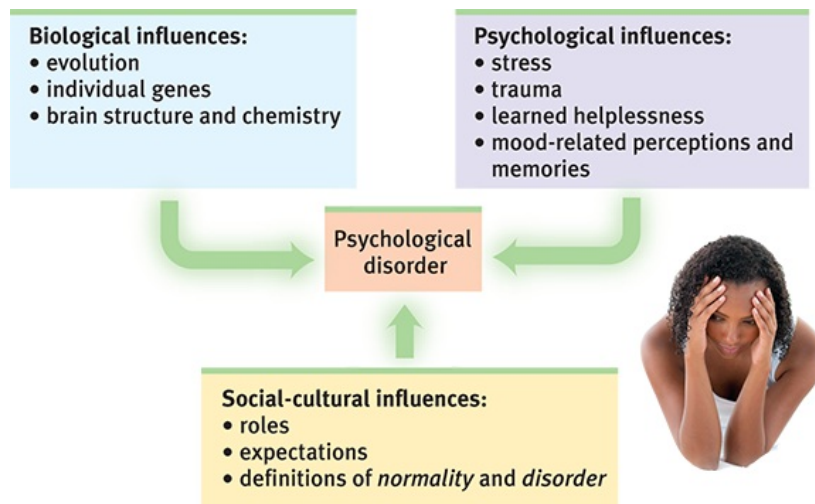

FIGURE 15.1 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Wavebreakmedia Ltd./Getty Images

FIGURE 15.1 The biopsychosocial approach to psychological disorders

Today's psychology studies how biological, psychological, and social-cultural factors interact to produce specific psychological disorders.

epigenetics the study of environmental influences on gene expression that occur without a DNA change.

RETRIEVAL PRACTICE

RP-2 Are psychological disorders universal or culture-specific?
Explain with examples.

ANSWER: Some psychological disorders are culture-specific. For example, anorexia nervosa occurs mostly in Western cultures, and *taijin kyofusho* appears largely in Japan. Other

disorders, such as schizophrenia, are universal—they occur in all cultures.

RP-3 What is the biopsychosocial approach, and why is it important in our understanding of psychological disorders?

ANSWER: Biological, psychological, and social-cultural influences combine to produce psychological disorders. This approach helps us understand that our well-being is affected by our genes, brain functioning, inner thoughts and feelings, and the influences of our social and cultural environment.

Classifying Disorders—and Labeling People

LOQ **15-3** How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

In biology, classification creates order. To classify an animal as a “mammal” says a great deal—that it is warm-blooded, has hair or fur, and produces milk to nourish its young. In psychiatry and psychology, too, classification orders and describes symptoms. To classify a person’s disorder as “schizophrenia” suggests that the person talks incoherently, has bizarre beliefs, shows either little emotion or inappropriate emotion, or is socially withdrawn.

“Schizophrenia” is a quick way to describe a complex disorder.

But diagnostic classification gives more than a thumbnail sketch of a person’s disordered behavior, thoughts, or feelings. In psychiatry and psychology, classification also aims to *predict* a disorder’s future course, *suggest* appropriate treatment, and *prompt research* into its causes. To study a disorder, we must first name and describe it.

In the United States, the most common tool for describing disorders and estimating how often they occur is the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, now in its fifth edition (**DSM-5**). Physicians and mental health workers use the detailed “diagnostic criteria and codes” in the DSM-5 to guide medical diagnoses and treatment. For example, a person may be diagnosed with and treated for

insomnia disorder if he or she meets all of the criteria in [TABLE 15.1](#). The DSM-5's diagnostic criteria and codes closely resemble those in the World Health Organization's *International Classification of Diseases* (ICD), making it easy to track worldwide trends in psychological disorders.

TABLE 15.1

Insomnia Disorder

• Feeling unsatisfied with amount or quality of sleep (trouble falling asleep, staying asleep, or returning to sleep)
• Sleep disruption causes distress or diminished everyday functioning
• Happens three or more nights each week
• Occurs during at least three consecutive months
• Happens even with sufficient sleep opportunities
• Independent from other sleep disorders (such as narcolepsy)
• Independent from substance use or abuse
• Independent from other mental disorders or medical conditions

Information from: American Psychiatric Association, 2013.

DSM-5 the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders.

In the new DSM-5, some diagnostic labels have changed. The conditions

formerly called “autism” and “Asperger’s syndrome” were combined under the label *autism spectrum disorder*. “Mental retardation” became *intellectual disability*. New disorders, such as *hoarding disorder* and *binge-eating disorder*, were added.

"I'm always like this, and my family was wondering if you could prescribe a mild depressant."

Sidney Harris

A book of case illustrations accompanying a previous DSM edition provided several examples for this chapter.

Some of the new or altered diagnoses are controversial. *Disruptive mood dysregulation disorder* is a new DSM-5 diagnosis for children “who exhibit persistent irritability and frequent episodes of behavior outbursts three or more times a week for more than a year.” Will this diagnosis assist parents who struggle with unstable children, or will it “turn temper tantrums into a mental disorder” and lead to overmedication, as the chair of the previous DSM edition warned (Frances, 2012)?

In real-world tests (*field trials*) assessing the reliability of the new DSM-5 categories, some diagnoses have fared well and others have fared poorly (Freedman et al., 2013). Clinician agreement on adult *posttraumatic stress disorder* and childhood *autism spectrum disorder*, for example, was near 70 percent. (If one psychiatrist or psychologist diagnosed someone with one of these disorders, there was a 70 percent chance that another mental health

worker would independently give the same diagnosis.) But for *antisocial personality disorder* and *generalized anxiety disorder*, agreement was closer to 20 percent.

Critics have long faulted the DSM for casting too wide a net and bringing “almost any kind of behavior within the compass of psychiatry” (Eysenck et al., 1983). Some now worry that the DSM-5’s even wider net will extend the pathologizing of everyday life. For example, the DSM has broadened the diagnostic criteria for [attention-deficit/hyperactivity disorder \(ADHD\)](#). For those who experience these challenging symptoms, diagnosis and treatment can be a relief and bring improved functioning (Kupfer, 2012; Maciejewski et al., 2016). However, critics suggest that the criteria are now too broad and may turn normal, childish rambunctiousness into a disorder (Frances, 2013, 2014). (See [Thinking Critically About: ADHD—Normal High Energy or Disordered Behavior?](#)) The DSM also now classifies severe grief following the death of a loved one as a possible *depressive disorder*. Critics suggest that such grief could instead simply be considered a “normal” reaction to tragic life events.

attention-deficit/hyperactivity disorder (ADHD) a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity.

Seeking a new but complementary approach to classification, the U.S. National Institute of Mental Health has established the Research Domain Criteria (RDoC) project (Insel et al., 2010; NIMH, 2017). The RDoC aims to bring “the power of modern research approaches in genetics, neuroscience, and behavioral science” to the study of psychological disorders (Insel & Lieberman, 2013). This framework helps organize disorders according to behaviors and brain activity related to negative or positive emotions, cognition, social relationships, and arousal and sleep. Exploring these dimensions improves psychologists’ ability to classify and treat disorders.

Other critics of classification register a more basic complaint—that diagnostic labels can be subjective, or even value judgments masquerading as science. Once we label a person, we view that person differently (Bathje & Pryor, 2011; Farina, 1982; Sadler et al., 2012b). Labels can change reality by putting us on alert for evidence that confirms our view. If we hear that a new co-worker is a nasty person, we may treat her suspiciously, leading her to respond as a mean-spirited person would. Teachers who were told certain students were “gifted” then acted in ways that elicited the behaviors they expected (Snyder, 1984). Labels can be self-fulfilling.

GRETCHEN ERTL/The New York Times/Redux

Struggles and recovery

During his campaign, Boston Mayor Martin Walsh spoke openly about his past struggles with alcohol. His story of recovery helped him win in 2014—the closest Boston mayoral election in decades.

The biasing power of labels was clear in a classic and controversial study. David Rosenhan (1973) and seven others went to hospital admissions offices, complaining (falsely) of “hearing voices” saying *empty*, *hollow*, and *thud*. Apart from this complaint and giving false names and occupations, they answered questions truthfully. All eight healthy people were misdiagnosed with disorders.

Should we be surprised? Surely not. As one psychiatrist noted, if someone swallows blood, goes to an emergency room, and spits it up, we wouldn’t

fault the doctor for diagnosing a bleeding ulcer. But what followed the diagnoses was startling. Until being released an average of 19 days later, those eight “patients” showed no other symptoms. Yet after analyzing their (quite normal) life histories, clinicians were able to “discover” the causes of their disorders, such as having mixed emotions about a parent. Even routine note-taking behavior was misinterpreted as a symptom.

Labels matter. In another study, people watched recorded interviews. If told the interviewees were job applicants, the viewers perceived them as normal (Langer & Abelson, 1974; Langer & Imber, 1980). Other viewers who were told they were watching cancer or psychiatric patients perceived the same interviewees as “different from most people.” Therapists who thought they were watching an interview of a psychiatric patient perceived him as “frightened of his own aggressive impulses,” a “passive, dependent type,” and so forth. A label can, as Rosenhan discovered, have “a life and an influence of its own.”

Labels also have power in everyday life. Getting a job or finding a place to rent can be a challenge for people recently released from a psychiatric hospital. Label someone as “mentally ill” and people may fear them as potentially violent. That reaction may fade as people better understand that many psychological disorders involve diseases of the brain, not failures of character. Public figures have helped foster this understanding by speaking openly about their own struggles with disorders such as depression and substance abuse. The more contact we have with people with disorders, the more accepting our attitudes become (Corrigan et al., 2014).

Despite their risks, diagnostic labels have benefits. They help mental health professionals to communicate about their cases and to study the causes and treatments of disorders. Clients are often relieved to learn that their suffering has a name, and that they are not alone in experiencing their symptoms.

“My sister suffers from a bipolar disorder and my nephew from schizoaffective disorder. There has, in fact, been a lot of depression and alcoholism in my family and, traditionally, no one ever spoke about it. It just wasn’t done. The stigma is toxic.”

**Actress Glenn Close,
“Mental Illness: The Stigma of Silence,” 2009**

Paramount Pictures/Photofest

Better portrayals

Old stereotypes are slowly being replaced in media portrayals of psychological disorders. Recent films offer fairly realistic depictions. *Iron Man 3* (2013) portrayed a main character, shown here, with posttraumatic stress disorder. *Black Swan* (2010) dramatized a lead character suffering a delusional disorder. *A Single Man* (2009) depicted depression.

“What’s the use of their having names,” the Gnat said, “if they won’t answer to them?”

“No use to them,” said Alice; “but it’s useful to the people that name them, I suppose.”

Lewis Carroll, *Through the Looking-Glass*, 1871

RETRIEVAL PRACTICE

RP-4 What is the value, and what are the dangers, of labeling individuals with disorders?

ANSWER: Therapists and others apply disorder labels to communicate with one another using a common language, and to share concepts during research. Clients may benefit from knowing that they are not the only ones with these symptoms. The

dangers of labeling people are that (1) people may begin to act as they have been labeled, and (2) the labels can trigger assumptions that will change people's behavior toward those labeled.

To test your ability to form diagnoses, try **PsychSim 6: Classifying Disorders**.

Does Disorder Equal Danger?

LOQ **15-5** Do psychological disorders predict violent behavior?

September 16, 2013, started like any other Monday at Washington, D.C.'s Navy Yard, with people arriving early to begin work. Then government contractor Aaron Alexis entered the building and began shooting. An hour later, 13 people were dead, including the shooter. Reports later confirmed that Alexis had a history of mental illness, and had stated that an “ultra low frequency attack is what I’ve been subject to for the last three months. And to be perfectly honest, that is what has driven me to this.” This devastating mass shooting, like the one in a Connecticut elementary school in 2012 and many others since then, reinforced public perceptions that people with psychological disorders pose a threat (Barry et al., 2013; Jorm et al., 2012). “People with mental illness are getting guns and committing these mass shootings,” said Speaker of the U.S. House Paul Ryan (2015). In one survey, 84 percent of Americans agreed that “increased government spending on mental health screening and treatment” would be a “somewhat” or “very” effective “approach to preventing mass shootings at schools” (Newport, 2012).

Do disorders actually increase risk of violence? And can clinicians predict who is likely to do harm? *No*. Most violent criminals are not mentally ill, and most mentally ill people are not violent (Fazel & Grann, 2006; Skeem et al., 2016). Moreover, clinical prediction of violence is unreliable. The few people with disorders who commit violent acts tend to be either those, like the Navy Yard shooter, who experience threatening delusions and hallucinated voices that command them to act, who have suffered a financial crisis or lost

relationship, or who abuse substances (Douglas et al., 2009; Elbogen et al., 2016; Fazel et al., 2009, 2010).

People with disorders are more likely to be *victims* than perpetrators of violence (Marley & Bulia, 2001). According to the U.S. Surgeon General's Office (1999, [p. 7](#)), "there is very little risk of violence or harm to a stranger from casual contact with an individual who has a mental disorder."

Psychological disorders only rarely lead to violent acts, and focusing gun restrictions only on mentally ill people will likely not reduce gun violence (Friedman, 2012). Better predictors of violence are use of alcohol or drugs, previous violence, and gun availability. The mass-killing shooters have one more thing in common: They tend to be young males.

Whether people with mental disorders who turn violent should be held responsible for their behavior remains controversial. U.S. President Ronald Reagan's near-assassin, John Hinckley, was sent to a hospital rather than to prison. The public was outraged. "Hinckley insane. Public mad," declared one headline. They were outraged again in 2011, when Jared Lee Loughner killed six people and injured several others, including U.S. Representative Gabrielle Giffords. Loughner was diagnosed with schizophrenia but nevertheless sentenced to life in prison without parole.

Which decision—hospital or prison—was correct? As we come to better understand the biological and environmental bases for all human behavior, from generosity to murder, when should we hold people accountable (or not) for their actions?

ADREES LATIF/REUTERS/Newscom

How to prevent mass shootings?

Following the Newtown, Connecticut, slaughter of 20 young children and 6 adults, people wondered: Could those at risk for violence be identified in advance by mental health workers and reported to police? Would laws that require such reporting discourage disturbed gun owners from seeking mental health treatment?

Rates of Psychological Disorders

LOQ **15-6** How many people have, or have had, a psychological disorder? Is poverty a risk factor?

Who is most vulnerable to psychological disorders? At what times of life? To answer such questions, many countries have conducted lengthy structured interviews with representative samples of thousands of their citizens. After asking hundreds of questions that probed for symptoms—“Has there ever been a period of two weeks or more when you felt like you wanted to die?”—the researchers have estimated the current, prior-year, and lifetime prevalence of various disorders.

How many people have, or have had, a psychological disorder? More than most of us suppose:

- A World Health Organization study—based on 90-minute interviews with thousands of people who were representative of their country’s population—estimated the number of prior-year mental disorders in 28 countries (Kessler et al., 2009). As [FIGURE 15.2](#) illustrates, the lowest rate of reported mental disorders was in Nigeria, the highest rate in the United States. Moreover, immigrants to the United States from Mexico, Africa, and Asia averaged better mental health than their U.S.-born counterparts with the same ethnic heritage (Breslau et al., 2007; Maldonado-Molina et al., 2011). For example, compared with Mexican-Americans born in the United States, Mexican-Americans who have recently immigrated are less at risk for mental disorders—a phenomenon known as the *immigrant paradox* (Schwartz et al., 2010).
- The U.S. National Institute of Mental Health (2015) has estimated that just under 1 in 5 adult Americans currently have a “mental, behavioral, or emotional disorder (excluding developmental and substance use disorders)” or have had one within the past year ([TABLE 15.2](#)).

FIGURE 15.2 Myers/DeWall, *Psychology*, 12e,

Data from Kessler et al., 2009

FIGURE 15.2 Prior-year prevalence of disorders in selected areas

From interviews in 28 countries. (Data from Kessler et al., 2009.)

TABLE 15.2

Percentage of Americans Reporting Selected Psychological Disorders in the Past Year

Psychological Disorder	Percentage
------------------------	------------

Depressive disorders or bipolar disorder	9.3
Phobia of specific object or situation	8.7
Social anxiety disorder	6.8
Attention-deficit/hyperactivity disorder (ADHD)	4.1
Posttraumatic stress disorder (PTSD)	3.5
Generalized anxiety disorder	3.1
Schizophrenia	1.1
Obsessive-compulsive disorder	1.0

Data from: National Institute of Mental Health, 2015.

What increases vulnerability to mental disorders? As [TABLE 15.3](#) indicates, there is a wide range of risk and protective factors for mental disorders. But one predictor of mental disorder—poverty—crosses ethnic and gender lines. The incidence of serious psychological disorders is 2.5 times higher among those below the poverty line (CDC, 2014a). Like so many other *correlations*, the poverty-disorder association raises further questions: Does poverty cause disorders? Or do disorders cause poverty? It is both, though the answer varies with the disorder. Schizophrenia understandably leads to poverty. Yet the stresses and demoralization of poverty can also precipitate disorders, especially depression in women and substance abuse in men (Dohrenwend et al., 1992). In one natural experiment investigating the poverty-pathology link, researchers tracked rates of behavior problems in North Carolina Native American children as economic development enabled a dramatic reduction in their community’s poverty rate. As the study began, children of poverty exhibited more deviant and aggressive behaviors. After four years, children whose families had moved above the poverty line exhibited a 40 percent decrease in behavior problems. Those who maintained their previous positions below or above the poverty line exhibited no change (Costello et al., 2003).

TABLE 15.3

Risk and Protective Factors for Mental Disorders

Risk Factors	Protective Factors
Academic failure	Aerobic exercise
Birth complications	Community offering empowerment, opportunity, and security
Caring for those who are chronically ill or who have a neurocognitive disorder	Economic independence
Child abuse and neglect	Effective parenting
Chronic insomnia	Feelings of mastery and control
Chronic pain	Feelings of security
Family disorganization or conflict	High self-esteem
Low birth weight	Literacy
Low socioeconomic status	Positive attachment and early bonding
Medical illness	Positive parent-child relationships
Neurochemical imbalance	Problem-solving skills
Parental mental illness	Resilient coping with stress and adversity
Parental substance abuse	Social and work skills
Personal loss and bereavement	Social support from family and friends
Poor work skills and habits	
Reading disabilities	
Sensory disabilities	
Social incompetence	
Stressful life events	
Substance abuse	
Trauma experiences	

Research from: World Health Organization (WHO, 2004b,c).

See the **Video: Correlational Studies** for a helpful tutorial about this research design. For a summary of disorder rates, engage online with **Concept Practice: Risks and Rates of Disorders**.

At what times of life do disorders strike? Usually by early adulthood.

“Over 75 percent of our sample with any disorder had experienced [their] first symptoms by age 24,” reported Lee Robins and Darrel Regier (1991, [p. 331](#)). Among the earliest to appear are the symptoms of antisocial personality disorder (median age 8) and of phobias (median age 10). Alcohol use disorder, obsessive-compulsive disorder, bipolar disorder, and schizophrenia symptoms appear at a median age near 20. Major depressive disorder often hits somewhat later, at a median age of 25.

RETRIEVAL PRACTICE

RP-5 What is the relationship between poverty and psychological disorders?

ANSWER: Poverty-related stresses can help trigger disorders, but disabling disorders can also contribute to poverty. Thus, poverty and disorder are often a chicken-and-egg situation; it's hard to know which came first.

REVIEW Introduction to Psychological Disorders

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Two major disorders that are found worldwide are schizophrenia and _____.

Anna is embarrassed that it takes her several minutes to parallel park her car. She usually gets out of the car once or twice to inspect her distance both from the curb and from the nearby cars. Should she worry about having a psychological disorder?

What is *susto*, and is this a culture-specific or universal psychological disorder?

A therapist says that psychological disorders are sicknesses, and

people with these disorders should be treated as patients in a hospital. This therapist believes in the _____ model.

Many psychologists reject the disorders-as-illness view and instead contend that other factors may also be involved—for example, the person's bad habits and poor social skills. This view represents the _____ approach.

- a. medical
- b. epigenetics
- c. biopsychosocial
- d. diagnostic

Why is the DSM, and the DSM-5 in particular, considered controversial?

One predictor of psychiatric disorders that crosses ethnic and gender lines is _____.

The symptoms of _____ appear around age 10; _____ tend[s] to appear later, around age 25.

- a. schizophrenia; bipolar disorder
- b. bipolar disorder; schizophrenia
- c. major depressive disorder; phobias
- d. phobias; major depressive disorder

Anxiety Disorders, OCD, and PTSD

Anxiety is part of life. Speaking in front of a class, peering down from a ladder, or waiting to learn the results of a final exam, any one of us might feel anxious. Anxiety may even cause us to avoid talking or making eye contact —“shyness,” we call it. Fortunately for most of us, our uneasiness is not intense and persistent. Some, however, are more prone to fear the unknown and to notice and remember perceived threats (Gorka et al., 2017; Mitte, 2008). When the brain’s danger-detection system becomes hyperactive, we are at greater risk for an *anxiety disorder*, and for two other disorders that involve anxiety: *obsessive-compulsive disorder (OCD)* and *posttraumatic stress disorder (PTSD)*.¹

Anxiety Disorders

LOQ **15-7** How do generalized anxiety disorder, panic disorder, and phobias differ?

The [anxiety disorders](#) are marked by distressing, persistent anxiety or by dysfunctional anxiety-reducing behaviors. For example, people with *social anxiety disorder* become extremely anxious in social settings where others might judge them, such as parties, class presentations, or even eating in public. To stave off anxious thoughts and feelings (including physical symptoms such as sweating and trembling), they may avoid going out at all. Even though this behavior reduces their anxiety, it is maladaptive—it does not help them cope with their world.

anxiety disorders psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety.

Let's take a closer look at three other anxiety disorders:

- *Generalized anxiety disorder*, in which a person is unexplainably and continually tense and uneasy.
- *Panic disorder*, in which a person experiences *panic attacks*—sudden episodes of intense dread—and fears the next episode's unpredictable onset.
- *Phobias*, in which a person is intensely and irrationally afraid of a specific object, activity, or situation.

Generalized Anxiety Disorder

For two years, Tom, a 27-year-old electrician, was bothered by dizziness, sweating palms, and heart palpitations. He felt on edge and sometimes found himself shaking. Tom was fairly successful in hiding his symptoms from his family and co-workers. But he allowed himself few other social contacts, and occasionally he had to leave work. Neither his family doctor nor a neurologist was able to find any physical problem.

Tom's unfocused, out-of-control, agitated feelings suggest **generalized anxiety disorder**, which is marked by excessive and uncontrollable worry that persists for six months or more. People with this condition (two-thirds are women) worry continually, and they are often jittery, agitated, and sleep-deprived (McLean & Anderson, 2009). Their gaze becomes fixated on potential threats (Pergamin-Hight et al., 2015). Concentration is difficult as attention switches from worry to worry. Their tension and apprehension may leak out through furrowed brows, twitching eyelids, trembling, perspiration, or fidgeting from *autonomic nervous system* arousal.

generalized anxiety disorder an anxiety disorder in which a person is continually tense, apprehensive, and in a state of *autonomic nervous system* arousal.

The person usually cannot identify, and therefore relieve or avoid, the tension's cause. To use Sigmund Freud's term, the anxiety is *free-floating* (not linked to a specific stressor or threat). Generalized anxiety disorder is

often accompanied by depressed mood, but even without depression it tends to be disabling (Hunt et al., 2004; Moffitt et al., 2007). Moreover, it may lead to physical problems, such as high blood pressure. As time passes, however, emotions tend to mellow, and by age 50, generalized anxiety disorder becomes fairly rare (Rubio & López-Ibor, 2007).

Panic Disorder

Many people can experience an intense anxiety that escalates into a terrifying panic attack—a minutes-long episode of intense fear that something horrible is about to happen. Irregular heartbeat, chest pains, shortness of breath, choking, trembling, or dizziness may accompany the panic. One woman recalled suddenly feeling

hot and as though I couldn't breathe. My heart was racing and I started to sweat and tremble and I was sure I was going to faint. Then my fingers started to feel numb and tingly and things seemed unreal. It was so bad I wondered if I was dying and asked my husband to take me to the emergency room. By the time we got there (about 10 minutes) the worst of the attack was over and I just felt washed out (Greist et al., 1986).

For the 3 percent of people with [panic disorder](#), panic attacks are recurrent. These anxiety tornados strike suddenly, wreak havoc, and disappear, but are not forgotten. Ironically, worries about anxiety—perhaps fearing another panic attack, or fearing anxiety-related symptoms in public—can amplify anxiety symptoms (Olatunji & Wolitzky-Taylor, 2009). After several panic attacks, people may avoid situations where panic might strike. If their fear is intense enough, people may develop *agoraphobia*—fear or avoidance of public situations from which escape might be difficult. Given such fear, people may avoid being outside the home, in a crowd, or in an elevator. Smokers have at least a doubled risk of panic disorder and greater symptoms when they do have an attack (Knuts et al., 2010; Zvolensky & Bernstein, 2005). Because nicotine is a stimulant, lighting up doesn't lighten us up.

panic disorder an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person may experience terror and

accompanying chest pain, choking, or other frightening sensations; often followed by worry over a possible next attack.

Sam Greenwood/Getty Images; Sam Greenwood/Getty Images

Panic on the course

Golfer Charlie Beljan experienced what he later learned were panic attacks during an important tournament. His thumping heartbeat and shortness of breath led him to think he was having a heart attack. But hospital tests revealed that his symptoms were not related to a physical illness. He recovered, went on to win \$846,000, and has become an inspiration to others.

Charles Darwin began suffering from panic disorder at age 28, after spending five years sailing the world. He moved to the country, avoided social gatherings, and traveled only in his wife's company. But the relative seclusion did free him to develop his evolutionary theory. "Even ill health," he reflected, "has saved me from the distraction of society and its amusements" (quoted in Ma, 1997).

Phobias

We all live with some fears. But people with **phobias** are consumed by a persistent, irrational fear and avoidance of some object, activity, or situation. *Specific phobias* may focus on animals, insects, heights, blood, or close spaces (**FIGURE 15.3**). Many people avoid the triggers (such as high places) that arouse their fear, and they manage to live with their phobia. Others are incapacitated by their efforts to avoid the feared situation. Marilyn, an otherwise healthy and happy 28-year-old, so feared thunderstorms that she felt anxious as soon as a weather forecaster mentioned possible storms later

in the week. If her husband was away when a storm was forecast, she often stayed with a close relative. During a storm, she hid from windows and buried her head to avoid seeing the lightning.

phobia an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation.

FIGURE 15.3 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Martin Harvey/Digital Vision/Getty Images; Data from Depla et al., 2008

FIGURE 15.3 Some common specific fears

Researchers surveyed Dutch people to identify the most common events or objects they feared. A strong fear becomes a phobia if it provokes a compelling but irrational desire to avoid the dreaded object or situation.

RETRIEVAL PRACTICE

RP-6 Unfocused tension, apprehension, and arousal are symptoms of _____ disorder.

ANSWER: generalized anxiety.

RP-7 Those who experience unpredictable periods of terror and intense dread, accompanied by frightening physical sensations, may be diagnosed with a _____ disorder.

ANSWER: panic.

RP-8 If a person is focusing anxiety on specific feared objects or situations, that person may have a _____.

ANSWER: phobia

Obsessive-Compulsive Disorder (OCD)

LOQ 15-8 What is OCD?

As with the anxiety disorders, we can see aspects of [obsessive-compulsive disorder \(OCD\)](#) in our everyday behavior. *Obsessive thoughts* are unwanted and so repetitive it may seem they will never go away. *Compulsive behaviors* are responses to those thoughts.

obsessive-compulsive disorder (OCD) a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both.

We are all at times obsessed with thoughts and we may behave compulsively. Have you ever felt a bit anxious about how your living space will appear to others and found yourself checking and cleaning one last time before your guests arrived? Or, perhaps worried about an upcoming exam, you caught yourself lining up books or devices “just so” before you began studying? Our lives are full of little rehearsals and fussy behaviors. They cross the fine line between normality and disorder when they *persistently interfere* with everyday living and cause distress. Checking that you locked the door is normal; checking 10 times is not. Washing your hands is normal; washing so often that your skin becomes raw is not. ([TABLE 15.4](#) offers more examples.) At some time during their lives, often during their late teens or twenties, about 2 percent of people cross that line from normal preoccupations and fussiness to debilitating disorder (Kessler et al., 2012). Although people know their anxiety-fueled obsessive thoughts are irrational, these thoughts can become so haunting, and the compulsive rituals so senselessly time-consuming, that effective functioning becomes impossible.

TABLE 15.4

Common Obsessions and Compulsions Among Children and Adolescents With Obsessive-

Compulsive Disorder

Thought or Behavior	Percentage Reporting Symptom
Obsessions (repetitive <i>thoughts</i>)	40
Concern with dirt, germs, or toxins	24
Something terrible happening (fire, death, illness)	17
Symmetry, order, or exactness	
Compulsions (repetitive <i>behaviors</i>)	85
Excessive hand washing, bathing, toothbrushing, or grooming	51
Repeating rituals (in/out of a door, up/down from a chair)	46
Checking doors, locks, appliances, car brakes, homework	
Data from: Rapoport, 1989.	

OCD is more common among teens and young adults than among older people (Samuels & Nestadt, 1997). A 40-year follow-up study of 144 Swedish people diagnosed with the disorder found that, for most, the obsessions and compulsions had gradually lessened, though only 1 in 5 had completely recovered (Skoog & Skoog, 1999).

Some people experience other OCD-related disorders, such as *hoarding disorder* (cluttering one's space with acquired possessions one can't let go), *body dysmorphic disorder* (preoccupation with perceived body defects), or—new words to impress your friends—*trichotillomania* (hair-pulling) or *excoriation disorder* (excessive skin-picking).

Michael Campanella/WireImage/Getty Images

Thriving with OCD

Music star Justin Timberlake has openly discussed his obsessive-compulsive disorder. He says that support from family and a rich sense of humor have helped him cope with the challenges.

For a 7-minute snapshot of one person's challenges with compulsive rituals, see the **Video: Obsessive-Compulsive Disorder–A Young Mother's Struggle**.

Posttraumatic Stress Disorder (PTSD)

LOQ **15-9** What is *PTSD*?

While serving his country in war, one soldier, Jesse, saw the killing “of children and women. It was just horrible for anyone to experience.” Back home, he suffered “real bad flashbacks” (Welch, 2005).

LYNN JOHNSON/National Geographic Creative

Bringing the war home

Hundreds of thousands of Iraq and Afghanistan war veterans have been diagnosed with PTSD or traumatic brain injury (TBI) (Veterans Administration, 2017). Many vets participate in an intensive recovery program using deep breathing, massage, and group and individual discussion techniques to treat their PTSD or TBI.

Jesse is not alone. In one study of 103,788 veterans returning from Iraq and Afghanistan, 25 percent were diagnosed with a psychological disorder (Seal et al., 2007). Some had *traumatic brain injuries (TBI)*, but the most frequent diagnosis was [posttraumatic stress disorder \(PTSD\)](#). Survivors of accidents, disasters, and violent and sexual assaults (including an estimated two-thirds of prostitutes) have also experienced PTSD symptoms (Brewin et al., 1999; Guo et al., 2017; Farley et al., 1998). Typical symptoms include recurring haunting memories and nightmares, laser-focused attention to possible threats, social withdrawal, jumpy anxiety, and trouble sleeping (Germain, 2013; Hoge et al., 2007; Yuval et al., 2017).

posttraumatic stress disorder (PTSD) a disorder characterized by haunting memories, nightmares, hypervigilance, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic experience.

About half of us will experience at least one traumatic event in our

lifetime. And many people will display *survivor resiliency*—by recovering after severe stress (Bonanno, 2004, 2005; Infurna & Luthar, 2016b). Although Friedrich Nietzsche’s (1889) surmise that “what does not kill me makes me stronger” is not true for all, some will even experience *posttraumatic growth* (see [Chapter 16](#)). Why do some 5 to 10 percent of people develop PTSD after a traumatic event, but others don’t (Bonanno et al., 2011)? One factor seems to be the amount of trauma-related emotional distress: The higher the distress, such as the level of physical torture suffered by prisoners of war, the greater the risk for posttraumatic symptoms (King et al., 2015; Ozer et al., 2003). Among American military personnel in Afghanistan, 7.6 percent of combatants developed PTSD, compared with 1.4 percent of noncombatants (McNally, 2012). Among survivors of the 9/11 terrorist attacks on New York’s World Trade Center, the rates of subsequent PTSD diagnoses for those who had been inside were double the rates of those who had been outside (Bonanno et al., 2006).

What else can influence PTSD development? Some people may have a more sensitive emotion-processing limbic system that floods their bodies with stress hormones (Kosslyn, 2005; Ozer & Weiss, 2004). Genes and gender also matter. Twins, compared with nontwin siblings, more commonly share PTSD cognitive risk factors (Gilbertson et al., 2006). And the odds of experiencing PTSD after a traumatic event are about two times higher for women than for men (Olf et al., 2007; Ozer & Weiss, 2004).

Some psychologists believe that PTSD has been overdiagnosed (Dobbs, 2009; McNally, 2003). Too often, say critics, PTSD gets stretched to include normal stress-related bad memories and dreams. And some well-intentioned procedures—such as “debriefing” people by asking them to revisit the experience and vent their emotions—may worsen stress reactions (Bonanno et al., 2010; Wakefield & Spitzer, 2002). Other research shows that reliving traumas (such as 9/11 or the Boston Marathon bombing) through media coverage sustains the stress response (Holman et al., 2014). Nevertheless, people diagnosed with PTSD can benefit from other therapies.

RETRIEVAL PRACTICE

RP-9 Those who express anxiety through unwanted repetitive thoughts or actions may have a(n) - disorder.

ANSWER: obsessive-compulsive.

RP-10 Those with symptoms of recurring memories and nightmares, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia for weeks after a traumatic event may be diagnosed with _____ disorder.

ANSWER: posttraumatic stress

Understanding Anxiety Disorders, OCD, and PTSD

LOQ **15-10** How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

Anxiety is both a feeling and a cognition—a doubt-laden appraisal of one’s safety or social skill. How do these anxious feelings and cognitions arise? Sigmund Freud’s psychoanalytic theory proposed that, beginning in childhood, people *repress* intolerable impulses, ideas, and feelings. Freud believed that this submerged mental energy sometimes leaks out in odd symptoms, such as anxious handwashing. Few of today’s psychologists share Freud’s interpretation of anxiety. Most believe that three modern perspectives—conditioning, cognition, and biology—are more helpful.

Conditioning

Through *classical conditioning*, our fear responses can become linked with formerly neutral objects and events. In a classic experiment, an infant —“Little Albert”—learned to fear furry objects that researchers paired with loud noises. In other experiments, researchers have created anxious animals by giving rats unpredictable electric shocks (Schwartz, 1984). The rats, like assault victims who report feeling anxious when returning to the scene of the crime, had learned to become uneasy in their lab environment. The lab had become a cue for fear.

Such research helps explain why anxious or traumatized people learn to associate their anxiety with certain cues (Bar-Haim et al., 2007; Duits et al.,

2015). In one survey, 58 percent of those with social anxiety disorder experienced their disorder after a traumatic event (Ost & Hugdahl, 1981). Anxiety or an anxiety-related disorder is more likely to develop when bad events happen unpredictably and uncontrollably (Field, 2006; Mineka & Oehlberg, 2008). Even a single painful and frightening event may trigger a full-blown phobia, thanks to two conditioning processes: classical conditioning's *stimulus generalization* and operant conditioning's *reinforcement*.

Stimulus generalization occurs when a person experiences a fearful event and later develops a fear of similar events. My [DM's] car was once struck by a driver who missed a stop sign. For months afterward, I felt a twinge of unease when any car approached from a side street. Likewise, I [ND] was watching a terrifying movie about spiders, *Arachnophobia*, when a severe thunderstorm struck and the theater lost power. For months, I experienced anxiety at the sight of spiders or cobwebs. Those fears eventually disappeared, but sometimes fears linger and grow. Marilyn's thunderstorm phobia may have similarly generalized after a terrifying or painful experience during a thunderstorm.

Reinforcement helps maintain learned fears and anxieties. Anything that enables us to avoid or escape a feared situation can reinforce maladaptive behaviors. Fearing a panic attack, we may decide not to leave the house. Reinforced by feeling calmer, we are likely to repeat that behavior in the future (Antony et al., 1992). So, too, with compulsive behaviors. If washing our hands relieves our feelings of anxiety, we may wash our hands again when those feelings return.

Cognition

Conditioning influences our feelings of anxiety, but so does cognition—our thoughts, memories, interpretations, and expectations. By observing others, we can learn to fear what they fear. Nearly all monkeys raised in the wild fear snakes, yet lab-raised monkeys do not. Surely, most wild monkeys do not actually suffer snake bites. Do they learn their fear through observation? To find out, Susan Mineka (1985, 2002) experimented with six monkeys raised in the wild (all strongly fearful of snakes) and their lab-raised offspring (virtually none of which feared snakes). After repeatedly observing their

parents or peers refusing to reach for food in the presence of a snake, the younger monkeys developed a similar strong fear of snakes. When the monkeys were retested three months later, their learned fear persisted. We humans similarly learn many of our own fears by observing others (Helsen et al., 2011; Olsson et al., 2007).

Hemera Technologies/PhotoObjects.net/360/Getty

Our past experiences shape our expectations and influence our interpretations and reactions. Whether we interpret the creaky sound simply as the wind or as a possible knife-wielding attacker determines whether we panic. People with anxiety disorders tend to be *hypervigilant*. They *attend* more to threatening stimuli. They more often *interpret* unclear stimuli as threatening: A pounding heart signals a heart attack; a lone spider near the bed indicates a likely infestation; an everyday disagreement with a friend or boss spells doom for the relationship. And they more often *remember* threatening events (Van Bockstaele et al., 2014). Anxiety is especially common when people cannot switch off such intrusive thoughts and perceive a loss of control and a sense of helplessness (Franklin & Foa, 2011).

Biology

There is, however, more to anxiety disorders, OCD, and PTSD than conditioning and cognitive processes alone. Why do some of us develop lasting phobias or PTSD after suffering traumas, but others do not? Why do we all learn some fears more readily than others? The answers lie in part in our biology.

GENES Among monkeys, fearfulness runs in families. A monkey reacts more strongly to stress if its close biological relatives are anxiously reactive (Suomi, 1986). So, too, with people. If one identical twin has an anxiety

disorder, the other is also at risk (Polderman et al., 2015). Even when raised separately, identical twins may develop similar phobias (Carey, 1990; Eckert et al., 1981). One pair of 35-year-old identical twins independently became so afraid of water that each would wade in the ocean backward and only up to her knees.

Given the genetic contribution to anxiety disorders, researchers are sleuthing the culprit genes. One research team identified 17 gene variations associated with typical anxiety disorder symptoms (Hovatta et al., 2005). Other teams have found genes associated specifically with OCD (Mattheisen et al., 2015; Taylor, 2013).

Some genes influence disorders by regulating brain levels of neurotransmitters. These include *serotonin*, which influences sleep, mood, and attending to threats (Canli, 2008; Pergamin-Hight et al., 2012), and *glutamate*, which heightens activity in the brain's alarm centers (Lafleur et al., 2006; Welch et al., 2007).

So genes matter. Some of us have genes that make us like orchids—fragile, yet capable of beauty under favorable circumstances. Others of us are like dandelions—hardy, and able to thrive in varied circumstances (Ellis & Boyce, 2008; Pluess & Belsky, 2013).

But experience affects gene expression. Among those with PTSD, a history of child abuse leaves long-term *epigenetic marks*, which are often organic molecules. These molecular tags attach to our chromosomes and turn certain genes on or off. Thus, experiences such as abuse can increase the likelihood that a genetic vulnerability to a disorder will be expressed (Mehta et al., 2013; Zannas et al., 2015). People who commit suicide show a similar epigenetic effect (Lockwood et al., 2015; McGowan et al., 2009).

THE BRAIN Our experiences change our brain, paving new pathways. Traumatic fear-learning experiences can leave tracks in the brain, creating fear circuits within the amygdala (Etkin & Wager, 2007; Herringa et al., 2013; Kolassa & Elbert, 2007). These fear pathways create easy inroads for more fear experiences (Armony et al., 1998).

Generalized anxiety disorder, panic attacks, phobias, OCD, and PTSD express themselves biologically as overarousal of brain areas involved in impulse control and habitual behaviors. These disorders reflect a brain danger-detection system gone hyperactive—producing anxiety when no

danger exists. In OCD, for example, when the brain detects that something is amiss, it seems to generate a mental hiccup of repeating thoughts (obsessions) or actions (compulsions) (Gehring et al., 2000). Brain scans of people with PTSD show higher-than-normal activity in the amygdala when they view traumatic images (Etkin & Wager, 2007). Brain scans of people with OCD reveal elevated activity in specific brain areas during behaviors such as compulsive hand washing, checking, ordering, or hoarding (Insel, 2010; Mataix-Cols et al., 2004, 2005). The *anterior cingulate cortex*, a brain region that monitors our actions and checks for errors, seems especially likely to be hyperactive (Maltby et al., 2005) ([FIGURE 15.4](#)).

FIGURE 15.4 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

FIGURE 15.4 An obsessive-compulsive brain

When people engaged in a challenging cognitive task, those with OCD showed the most activity in the anterior cingulate cortex in the brain's frontal area (Maltby et al., 2005).

Some antidepressant drugs dampen this fear circuit activity and its associated obsessive-compulsive behavior. Fears can also be blunted by giving people drugs as they recall and then rerecord (“reconsolidate”) a traumatic experience (Kindt et al., 2009; Norberg et al., 2008). Although they don’t forget the experience, the associated emotion is largely erased.

NATURAL SELECTION We seem biologically prepared to fear threats faced by our ancestors. Our phobias focus on such specific fears: spiders, snakes, and other animals; enclosed spaces and heights; storms and darkness.

Those fearless about these occasional threats were less likely to survive and leave descendants. Even in Britain, with only one poisonous snake species, people often fear snakes. Nine-month-old infants attend more to sounds signaling ancient threats (hisses, thunder) than they do to sounds representing modern dangers (a bomb exploding, breaking glass) (Erlich et al., 2013). It is easy to condition and hard to extinguish fears of such “evolutionarily relevant” stimuli (Coelho & Purkis, 2009; Davey, 1995; Öhman, 2009). Some of our modern fears can also have an evolutionary explanation. A fear of flying may be rooted in our biological predisposition to fear confinement and heights.

Compare our easy-to-learn fears with those we *do not* easily learn. World War II air raids, for example, produced remarkably few lasting phobias. As the air blitzes continued, the British, Japanese, and German populations did not become more and more panicked. Rather, they grew increasingly indifferent to planes outside their immediate neighborhoods (Mineka & Zinbarg, 1996). Evolution has not prepared us to fear bombs dropping from the sky.

Just as our phobias focus on dangers faced by our ancestors, our compulsive acts typically exaggerate behaviors that contributed to our species’ survival. Grooming had survival value. Gone wild, it becomes compulsive hair pulling. So too with washing up, which becomes ritual hand washing. And checking territorial boundaries becomes checking and rechecking already locked doors (Rapoport, 1989). Although natural selection shaped our behaviors, when taken to an extreme, these behaviors can interfere with daily life.

Peter Bohler/Redux

Fearless

The biological perspective helps us understand why most people have more fear of heights than does Alex Honnold, shown here in 2017 becoming the first person to free solo climb (no safety ropes) Yosemite National Park's El Capitan granite wall.

RETRIEVAL PRACTICE

RP-11 Researchers believe that conditioning and cognitive processes are aspects of learning that contribute to anxiety-related disorders. What *biological* factors also contribute to these disorders?

ANSWER: Biological factors include inherited temperament differences and other gene variations; experience-altered brain pathways; and outdated, inherited responses that had survival value for our distant ancestors.

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Anxiety that takes the form of an irrational and maladaptive fear of a specific object, activity, or situation is called a _____.

An episode of intense dread that can be accompanied by chest pains, choking sensations, or other frightening sensations is called

- a. an obsession.
- b. a compulsion.
- c. a panic attack.
- d. a specific phobia.

Marina became consumed with the need to clean the entire house and refused to participate in any other activities. Her family consulted a therapist, who diagnosed her as having _____ disorder.

When a person with an anxiety disorder eases anxiety by avoiding or escaping a situation that inspires fear, this is called

- a. free-floating anxiety.
- b. reinforcement.

- c. an epigenetic mark.
- d. hypervigilance.

The learning perspective proposes that phobias are

- a. the result of individual genetic makeup.
- b. a way of repressing unacceptable impulses.
- c. conditioned fears.
- d. a symptom of having been abused as a child.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury

LOQ **15-11** How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

In the past year, have you at some time “felt so depressed that it was difficult to function”? If so, you were not alone. In one national survey, 31 percent of American college students answered *Yes* (ACHA, 2009). You might feel deeply discouraged about the future, dissatisfied with your life, or socially isolated. You may lack the energy to get things done, to see people, or even to force yourself out of bed. You may be unable to concentrate, eat, or sleep normally. You may even wonder if you would be better off dead. Perhaps academic success came easily to you before, but now you find that disappointing grades jeopardize your goals. Maybe social stress, such as loneliness, feeling you are the target of prejudice, or experiencing a romantic breakup, have plunged you into despair. And perhaps low self-esteem increases your brooding, worsening your self-torment (Orth et al., 2016). Likely you think you are more alone in having such negative feelings than you really are (Jordan et al., 2011). Most of us have had some direct or indirect experience with depression: Misery has more company than most suppose.

Brad Wenner/Getty Images

Joy, contentment, sadness, and despair exist at different points on a continuum, points at which any of us may find ourselves at any given moment. To feel bad in reaction to profoundly sad events is to be in touch with reality. In such times, sadness is like a car's low-fuel light—a warning signal that we should stop and take appropriate measures. Biologically speaking, life's purpose is not happiness but survival and reproduction. Coughing, vomiting, swelling, and pain protect the body from dangerous toxins and stimuli. Similarly, depression resembles a sort of psychic hibernation: It slows us down, prompting us, when losing a relationship or blocked from a goal, to conserve energy (Beck & Bredemeier, 2016; Gershon et al., 2016). There is sense to suffering. When we grind temporarily to a halt and reassess our life, as depressed people do, we can redirect our energy in more promising ways (Watkins, 2008). Even mild sadness helps people process and recall faces more accurately (Hills et al., 2011). They also tend to pay more attention to details, think more critically (with less gullibility), and make better decisions (Forgas, 2009, 2013).

“My life had come to a sudden stop. I was able to breathe, to eat, to drink, to sleep. I could not, indeed, help doing so; but there was no real life in me.”

Leo Tolstoy, *My Confession*, 1887

But sometimes this response, taken to an extreme, can become seriously maladaptive and signal a disorder. The difference between a blue mood after bad news and a depression-related disorder is like the difference between breathing heavily after a hard run and being chronically exhausted.

“If someone offered you a pill that would make you permanently happy, you would be well advised to run fast and run far. Emotion is a compass that tells us what to do, and a compass that is perpetually stuck on NORTH is worthless.”

Daniel Gilbert, “The Science of Happiness,” 2006

In this section, we consider three disorders in which depression impairs daily living, focusing on the two principle forms. *Major depressive disorder*

is a state of hopelessness and lethargy lasting several weeks or months. *Persistent depressive disorder* is similar, but with milder depressive symptoms that last a much longer period of time. *Bipolar disorder* (formerly called *manic-depressive disorder*) is when a person alternates between depression and overexcited hyperactivity.

Major Depressive Disorder

Major depressive disorder occurs when at least five signs of depression (including either depressed mood or loss of interest or pleasure) last two or more weeks ([TABLE 15.5](#)). To sense what major depressive disorder feels like, imagine combining the anguish of grief with the sluggishness of bad jet lag. If stress-related anxiety is a “crackling, menacing brushfire,” noted biologist Robert Sapolsky (2003), “depression is a suffocating heavy blanket thrown on top of it.”

major depressive disorder a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure.

TABLE 15.5

Diagnosing Major Depressive Disorder

The DSM-5 classifies major depressive disorder as the presence of at least five of the following symptoms over a 2-week period of time (minimally including depressed mood or reduced interest) (American Psychiatric Association, 2013).

- Depressed mood most of the time
- Dramatically reduced interest or enjoyment in most activities most of the time
- Significant challenges regulating appetite and weight

• Significant challenges regulating sleep
• Physical agitation or lethargy
• Feeling listless or with much less energy
• Feeling worthless, or feeling unwarranted guilt
• Problems in thinking, concentrating, or making decisions
• Thinking repetitively of death and suicide

Adults diagnosed with persistent depressive disorder (also called *dysthymia*) have experienced a mildly depressed mood more often than not for two years or more (American Psychiatric Association, 2013). They also display at least two of the following symptoms:

- Difficulty with decision making and concentration
- Feeling hopeless
- Poor self-esteem
- Reduced energy levels
- Problems regulating sleep
- Problems regulating appetite

Depression is the number-one reason people seek mental health services. Indeed, the World Health Organization declared depression “the top cause of disability in the world today” (CBC News, 2017; WHO, 2017b). In one survey conducted in 21 countries, 4.6 percent of people interviewed were experiencing moderate or severe depression (Thornicroft et al., 2017).

For some people, depressive symptoms may have a *seasonal pattern*, returning each winter. When asked “Have you cried today?” Americans have agreed more often in the winter ([TABLE 15.6](#)). But some researchers have questioned how often this seasonal pattern occurs (Traffanstedt et al., 2016),

so stay tuned.

TABLE 15.6
Percentage Answering Yes
When Asked “Have You Cried
Today?”

	Percentage who cried	
	Men	Women
August	4%	7%
December	8%	21%
Data from: Time/CNN survey, 1994.		

Bipolar Disorder

Our genes dispose some of us, more than others, to respond emotionally to good and bad events (Whisman et al., 2014). In [bipolar disorder](#), people bounce from one emotional extreme to the other (week to week, rather than day to day or moment to moment). When a depressive episode ends, a euphoric, overly talkative, wildly energetic, and extremely optimistic state called [mania](#) follows. But before long, the mood either returns to normal or plunges again into depression.

bipolar disorder a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.)

mania a hyperactive, wildly optimistic state in which dangerously poor judgment is common.

During the manic phase, people with bipolar disorder typically have little

need for sleep. They show fewer sexual inhibitions. Their positive emotions persist abnormally (Gruber, 2011; Gruber et al., 2013). Their speech is loud, flighty, and hard to interrupt. They find advice irritating. Yet they need protection from their own poor judgment, which may lead to reckless spending or unsafe sex. Thinking fast feels good, but it also increases risk taking (Chandler & Pronin, 2012; Pronin, 2013).

Life as a Two-Headed Beast: Bipolar, Abigail Southworth

Bipolar disorder

Artist Abigail Southworth illustrated her experience of bipolar disorder.

In milder forms, mania's energy and flood of ideas can fuel creativity. Clusters of genes associated with high creativity increase the likelihood of having bipolar disorder, and risk factors for developing bipolar disorder predict greater creativity (Baas et al., 2016; Power et al., 2015). George Frideric Handel, who may have suffered from a mild form of bipolar disorder, composed his nearly four-hour-long *Messiah* (1742) during three weeks of intense, creative energy (Keynes, 1980). Robert Schumann composed 51 musical works during two years of mania (1840 and 1849) but none during 1844, when he was severely depressed (Slater & Meyer, 1959). Those who rely on precision and logic, such as architects, designers, and journalists, suffer bipolar disorder less often than do those who rely on emotional expression and vivid imagery (Ludwig, 1995). Composers, artists, poets, novelists, and entertainers seem especially prone (Jamison, 1993, 1995; Kaufman & Baer, 2002; Ludwig, 1995). Indeed, one analysis of over a million individuals showed that the only psychiatric condition linked to working in a creative profession was bipolar disorder (Kyaga et al., 2013).

Dave Bedrosian/ZUMA Press/Newscom; George C. Beresford/Getty Images; The Granger Collection, NYC—All Rights Reserved.

Creativity and bipolar disorder

There have been many creative artists, composers, writers, and musical performers with bipolar disorder.

Though bipolar disorder is much less common than major depressive disorder, it is often more dysfunctional, claiming twice as many lost workdays yearly (Kessler et al., 2006). It is also a potent predictor of suicide (Schaffer et al., 2015). Unlike major depressive disorder, bipolar disorder afflicts as many men as women. The diagnosis has risen among adolescents, whose mood swings, sometimes prolonged, may vary from raging to bubbly. In the decade between 1994 and 2003, bipolar diagnoses in Americans under the age of 20 revealed an astonishing 40-fold increase—from an estimated 20,000 to 800,000 (Carey, 2007; Flora & Bobby, 2008; Moreno et al., 2007). Americans are twice as likely as people of other countries to have ever had a diagnosis of bipolar disorder (Merikangas et al., 2011). The new DSM-5 classifications have, however, begun to reduce the number of child and adolescent bipolar diagnoses: Some of those who are persistently irritable and who have frequent and recurring behavior outbursts are now instead diagnosed with *disruptive mood dysregulation disorder* (Faheem et al., 2017).

Terry Gatanis/ZUMA Press/Newscom

Life after depression

J. K. Rowling, author of the Harry Potter books, reported suffering acute depression—a “dark time,” with suicidal thoughts—between ages 25 and 28. It was a “terrible place,” she said, but it formed a foundation that allowed her “to come back stronger” (McLaughlin, 2010).

Understanding Depressive Disorders and Bipolar Disorder

LOQ **15-12** How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

Today’s psychologists continue to sleuth why people have depressive disorders and bipolar disorder, and to design more effective ways to treat and prevent them. Here, we focus primarily on depressive disorders. One research group summarized the facts that any theory of depression must explain,

including the following (Lewinsohn et al., 1985, 1998, 2003):

- ***Behavioral and cognitive changes accompany depression.*** People trapped in a depressed mood become inactive and feel alone, empty, and without a bright or meaningful future (Bullock & Murray, 2014; Khazanoy & Ruscio, 2016; Smith & Rhodes, 2014). They avoid positive information and attend selectively to negative events (Peckham et al., 2010; Winer & Salem, 2016). They more often recall negative information. They expect negative outcomes (my team will lose, my grades will fall, my love will fail). When the depression lifts, these behavioral and cognitive accompaniments disappear. Nearly half the time, people also exhibit symptoms of another disorder, such as anxiety or substance abuse.
- ***Depression is widespread.*** Worldwide, 350 million people have major depressive disorder and 60 million people have bipolar disorder (WHO, 2017a). At some point during their lifetime, depression has plagued 11 percent of Canadian 15-to-24-year olds (Findlay, 2017). Depression's commonality suggests that its causes, too, must be common.
- ***Women's risk of major depressive disorder is nearly double men's.*** In 2009, when Gallup pollsters asked more than a quarter-million Americans if they had ever been diagnosed with depression, 13 percent of men and 22 percent of women said they had (Pelham, 2009). When Gallup asked Americans if they had experienced sadness "during a lot of the day yesterday," 17 percent of men and 28 percent of women answered Yes (Mendes & McGeeney, 2012). The depression gender gap—with U.S. women experiencing depression 1.7 times more often than men (CDC, 2014a)—has been found worldwide ([FIGURE 15.5](#)). The trend begins in adolescence; preadolescent girls are not more depression-prone than are boys (Kuehner, 2017). After reaching puberty, girls also become more vulnerable than boys to eating disorders, self-injury, and anxiety (Mendle et al., 2016). Menopause—more specifically, "the 5 or 6 years surrounding the last menstrual period"—is also a time of women's increased depression risk, though in later life, the depression gender gap diminishes (Gordon et al., 2016; Patten et al., 2016).

FIGURE 15.5 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Bromet et al., 2011.

FIGURE 15.5 Gender and major depressive disorder

Interviews with 89,037 adults in 18 countries (10 of which are shown here) confirm what many smaller studies have found: Women's risk of major depressive disorder is nearly double men's.

The factors that put women at risk for depression (genetic predispositions, child abuse, low self-esteem, marital problems, and so forth) similarly put men at risk (Kendler et al., 2006). Yet women are more vulnerable to disorders involving internalized states, such as depression, anxiety, and inhibited sexual desire. Women experience more situations that increase their risk for depression, such as receiving less pay for equal work, juggling multiple roles, and caring for children and elderly family members (Freeman & Freeman, 2013). Men's disorders tend to be more external—alcohol use disorder, and disorders related to antisocial conduct and lack of impulse control. When women get sad, they often get sadder than men do. When men get mad, they often get madder than women do.

- ***Most major depressive episodes self-terminate.*** Therapy often helps and tends to speed recovery. But even without professional help, most people recover from depression and return to normal. The plague of depression comes and, a few weeks or months later, it goes, though for some (about half), it eventually returns (Curry et al., 2011; Klein & Kotov, 2016). Only about 20 percent experience chronic depression (Klein, 2010). On average, a person with major depressive disorder today will spend about three-fourths of the next decade in a normal, nondepressed state (Furukawa et al., 2009). In one study of over 20,000 Canadians, an enduring recovery was more likely if the first episode struck later in life, there was no prior history of depression, people experienced minimal physical or psychological stress, and they had ample social support (Fuller-Thomson et al., 2016).
- ***Stressful events related to work, marriage, and close relationships often***

precede depression. As anxiety is a response to the threat of future loss, depression is often a response to past and current stress. Experiencing childhood abuse doubles a person's risk of adult depression (Nelson et al., 2017). About 1 person in 4 diagnosed with depression has been brought down by a significant loss or trauma, such as a loved one's death, a ruptured marriage, a physical assault, or a lost job (Kendler et al., 2008; Monroe & Reid, 2009; Orth et al., 2009; Wakefield et al., 2007). Moving to a new culture also increases risk for depression, especially among younger people who have not yet formed their identities (Zhang et al., 2013). One long-term study (Kendler, 1998) tracked rates of depression in 2000 people. The risk of depression ranged from less than 1 percent among those who had experienced no stressful life event in the preceding month to 24 percent among those who had experienced three such events in that month. For some, grappling with life's minor daily stressors can also negatively impact mental health. People who overreacted to minor stressors, such as a broken appliance, were more often depressed 10 years later (Charles et al., 2013).

- ***Compared to generations past, depression strikes earlier (now often in the late teens) and affects more people, with the highest rates among young adults in developed countries.*** Although adolescent depression rates have recently leveled off, this trend has been reported in Canada, the United States, England, France, Germany, Italy, Lebanon, New Zealand, Puerto Rico, and Taiwan (Cross-National Collaborative Group, 1992; Kessler et al., 2010; Olfson et al., 2015). In one study, 12 percent of Australian adolescents reported symptoms of depression (Sawyer et al., 2000). Most hid it from their parents, almost 90 percent of whom perceived their depressed teen as *not* suffering depression. In North America, young adults are three times more likely than their grandparents to report having recently—or ever—suffered depression (despite the grandparents' many more years of being at risk). The increase may reflect a cultural difference of today's young adults' greater willingness to disclose depression.

Armed with these facts, today's researchers propose biological and cognitive explanations of depression, often combined in a biopsychosocial perspective.

For a 9-minute story about one young man's struggle with depression, see the **Video: Depression**.

The Biological Perspective

Depression is a whole-body disorder. It involves genetic predispositions and biochemical imbalances, as well as negative thoughts and a gloomy mood.

GENETIC INFLUENCES Depressive disorders and bipolar disorder run in families. As one researcher noted, emotions are “postcards from our genes” (Plotkin, 1994). The risk of being diagnosed with one of these disorders increases if your parent or sibling has the disorder (Sullivan et al., 2000; Weissman et al., 2016). If one identical twin is diagnosed with major depressive disorder, the chances are about 1 in 2 that at some time the other twin will be, too. If one identical twin has bipolar disorder, the chances of a similar diagnosis for the co-twin are even higher—7 in 10—even for those twins raised apart (DiLalla et al., 1996). Summarizing the major twin studies, one research team estimated the heritability of major depressive disorder—the extent to which individual differences are attributable to genes—at 40 percent (Polderman et al., 2015; see also [FIGURE 15.6](#) for another study's similar heritability findings for this and other disorders).

FIGURE 15.6 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 15.6 The heritability of various psychological disorders

Using aggregated data from studies of identical and fraternal twins, researchers estimated the heritability of bipolar disorder, schizophrenia, anorexia nervosa, major depressive disorder, and generalized anxiety disorder (Bienvenu et al., 2011). (Heritability was calculated by a formula that compares the extent of similarity among identical versus

fraternal twins.)

To tease out the genes that put people at risk for depression, some researchers have turned to *linkage analysis*. First, geneticists find families in which the disorder appears across several generations. Next, the researchers examine DNA from affected and unaffected family members, looking for differences. Linkage analysis points them to a chromosome neighborhood; “A house-to-house search is then needed to find the culprit gene” (Plomin & McGuffin, 2003). But depression is a complex condition. Many genes work together, producing a mosaic of small effects that interact with other factors to put some people at greater risk. Researchers continue to identify culprit gene variations that may open the door to more effective drug therapy (Hyde et al., 2016; Power et al., 2017; Ripke et al., 2013).

THE DEPRESSED BRAIN Scanning devices let us eavesdrop on the brain’s activity during depressed and manic states. One study gave 13 elite Canadian swimmers the wrenching experience of watching a video of the swim in which they failed to make the Olympic team or failed at the Olympic games (Davis et al., 2008). Functional MRI scans showed the disappointed swimmers experiencing brain activity patterns similar to those of people with depressed moods.

Many studies have found diminished brain activity during slowed-down depressive states, and more activity during periods of mania (**FIGURE 15.7**). Depression can cause the brain’s reward centers to become less active (Miller et al., 2015; Stringaris et al., 2015). During positive emotions, the left frontal lobe and an adjacent reward center become more active (Davidson et al., 2002; Heller et al., 2009; Robinson et al., 2012).

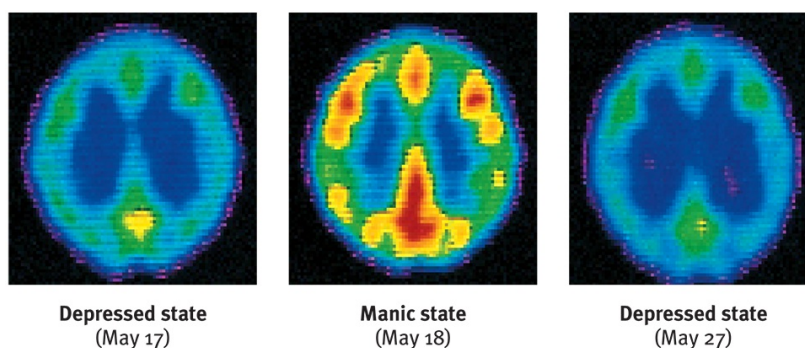

FIGURE 15.7 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Courtesy of Drs. Lewis Baxter and Michael E. Phelps, UCLA School of Medicine

FIGURE 15.7 The ups and downs of bipolar disorder

These top-facing PET scans show that brain energy consumption rises and falls with the patient's emotional switches. Red areas are where the brain rapidly consumes glucose.

Neuroscientists have also discovered altered brain structures in people with bipolar disorder. These studies discovered decreased white matter (myelinated axons) and enlarged fluid-filled ventricles (Arnone et al., 2009; Hibar et al., 2016).

Neurotransmitter systems also influence depressive disorders and bipolar disorder. *Norepinephrine*, which increases arousal and boosts mood, is scarce during depression and overabundant during mania. Drugs that decrease mania reduce norepinephrine.

Serotonin is also scarce or inactive during depression (Carver et al., 2008). One well-publicized study of New Zealand young adults found that the recipe for depression combined two necessary ingredients—significant life stress plus a variation of a serotonin-controlling gene (Caspi et al., 2003; Moffitt et al., 2006). Depression arose from the combination of an adverse environment plus a genetic susceptibility, but not from either alone. But stay tuned: The story of gene-environment interactions is still being written, as other researchers debate the reliability of this result (Culverhouse et al., 2013; Karg et al., 2011; Munafò et al., 2009; Uher & McGuffin, 2010).

Microbes and the mind

Digestive system bacteria produce neurotransmitters that influence human emotions and social interactions (Dinan et al., 2015; Kaplan et al., 2015; Nowakowski et al., 2016).

Drugs that relieve depression tend to increase norepinephrine or serotonin supplies by blocking either their reuptake (as Prozac, Zoloft, and Paxil do with serotonin) or their chemical breakdown. Repetitive physical exercise, such as jogging, reduces depression in part because it increases serotonin, which affects mood and arousal (Airan et al., 2007; Ilardi, 2009; Jacobs, 1994). In one study, running for two hours increased brain activation in regions associated with euphoria (Boecker et al., 2008). To run away from a bad mood, you can use your own two feet.

NUTRITIONAL EFFECTS What's good for the heart is also good for the brain and mind. People who eat a heart-healthy "Mediterranean diet" (heavy on vegetables, fish, and olive oil) have a comparatively low risk of developing heart disease, stroke, late-life cognitive decline, and depression—all of which are associated with inflammation (Kaplan et al., 2015; Psaltopoulou et al., 2013; Rechenberg, 2016). Excessive alcohol use also correlates with depression, partly because depression can increase alcohol use but mostly because alcohol misuse *leads* to depression (Fergusson et al., 2009).

The Social-Cognitive Perspective

Biological influences contribute to depression, but in the nature–nurture dance, our life experiences also play a part. Diet, drugs, stress, and other environmental influences lay down *epigenetic marks*, molecular genetic tags that can turn certain genes on or off. Animal studies suggest that long-lasting epigenetic influences may play a role in depression (Nestler, 2011).

Thinking matters, too. The *social-cognitive perspective* explores how people's assumptions and expectations influence what they perceive. Many depressed people view life through the dark glasses of low self-esteem (Orth et al., 2016). Their intensely negative assumptions about themselves, their situation, and their future lead them to magnify bad experiences and minimize good ones (Wenze et al., 2012). Listen to Norman, a Canadian university professor, recalling his depression:

I [despaired] of ever being human again. I honestly felt subhuman, lower than the lowest vermin. Furthermore, I was self-deprecatory and could not understand why anyone would want to associate with me, let alone love me. . . . I was positive that I was a fraud and a phony and that I didn't deserve my Ph.D. . . . I didn't deserve the research grants I had been awarded; I couldn't understand how I had written books and journal articles. . . . I must have conned a lot of people. (Endler, 1982, pp. 45–49)

Expecting the worst, depressed people magnify bad experiences and minimize good ones (Wenze et al., 2012). Their *self-defeating beliefs* and their *negative explanatory style* feed their depression.

NEGATIVE THOUGHTS, NEGATIVE MOODS, AND GENDER

Women may respond more strongly to stress (Hankin & Abramson, 2001;

Mazure et al., 2002; Nolen-Hoeksema, 2001, 2003). For example, 38 percent of women and 17 percent of men entering American colleges and universities have reported feeling at least occasionally “overwhelmed by all I have to do” (Pryor et al., 2006). Relationship stresses also affect teen girls more than boys (Hamilton et al., 2015).

This gender stress difference may help explain why, beginning in their early teens, women have been nearly twice as vulnerable to depression. Susan Nolen-Hoeksema (2003) related women’s higher risk of depression to what she described as their tendency to ruminate or *overthink*. Staying focused on a problem (thanks to the continuous firing of a frontal lobe area that sustains attention)—can be adaptive (Altamirano et al., 2010; Andrews & Thomson, 2009a,b). But relentless, self-focused **rumination** can distract us, increase negative emotion, and disrupt daily activities (Johnson et al., 2016; Kircanski et al., 2015; Yang et al., 2017). Comparisons can also feed misery. While Josh is happily playing video games, lonely Lauren scrolls through her social media feed and sees Maria having a blast at a party, Angelique enjoying a family vacation, and Tyra looking super in a swimsuit. In response, Lauren broods: “My life is terrible.”

rumination compulsive fretting; *overthinking* our problems and their causes.

“I think I, like a lot of people, have that type of brain where I find it interesting or fulfilling to worry about something.”

Comedian Maria Bamford

Even so, why do life’s unavoidable failures lead only some people to become depressed? The answer lies partly in their *explanatory style*—who or what they blame for their failures. Think of how you might feel if you failed a test. If you can externalize the blame (“What an unfair test!”), you are more likely to feel angry. If you blame yourself, you probably will feel stupid and depressed.

Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

Rumination runs wild

It's normal to think about our flaws. But dwelling constantly on negative thoughts—particularly negative thoughts about ourselves—makes it difficult to believe in ourselves and solve problems. People sometimes seek therapy to reduce their rumination.

So it is with depressed people, who often explain bad events in terms that are *stable* (“It’s going to last forever”), *global* (“It’s going to affect everything I do”), and *internal* (“It’s all my fault”) ([FIGURE 15.8](#)). Depression-prone people respond to bad events in an especially self-focused, self-blaming way (Huang, 2015; Mor & Winquist, 2002; Wood et al., 1990a,b). When they describe themselves, their brains show extra activity in a region that processes self-relevant information (Sarsam et al., 2013). Their self-esteem is also more plastic—it climbs with praise and plummets with threats (Butler et al., 1994).

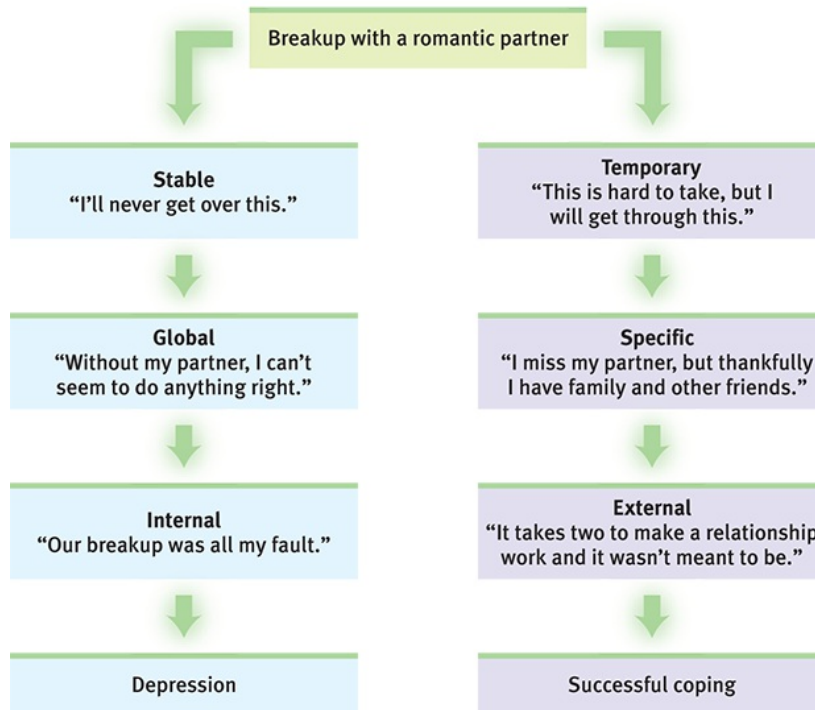

FIGURE 15.8 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 15.8 Explanatory style and depression

After a negative experience, a depression-prone person may respond with a negative explanatory style.

Self-defeating beliefs may arise from *learned helplessness*, the hopelessness and passive resignation humans and other animals learn when they experience uncontrollable painful events (Maier & Seligman, 2016). Pessimistic, overgeneralized, self-blaming attributions may create a depressing sense of hopelessness (Abramson et al., 1989; Panzarella et al., 2006). As Martin Seligman has noted, “A recipe for severe depression is preexisting pessimism encountering failure” (1991, [p. 78](#)). What then might we expect of new college students who exhibit a pessimistic explanatory style? Lauren Alloy and her colleagues (1999) monitored several hundred students every 6 weeks for 2.5 years. Among those identified as having a pessimistic thinking style, 17 percent had a first episode of major depression, as did only 1 percent of those who began college with an optimistic thinking style.

"You should never engage in unsupervised introspection."

To explore your own thinking style, engage online with **Assess Your Strengths: How Hopeful Are You? Why Is This Important?**

Why is depression so common among young Westerners? Seligman (1991, 1995) pointed to the rise of individualism and the decline of commitment to religion and family. In non-Western cultures, where close-knit relationships and cooperation are the norm, major depressive disorder is less common and less tied to self-blame over personal failure (Ferrari et al., 2013; WHO, 2004a). In Japan, for example, depressed people instead tend to report feeling shame over letting others down (Draguns, 1990a).

Critics note a chicken-and-egg problem nesting in the social-cognitive explanation of depression. Which comes first? The pessimistic explanatory style, or the depressed mood? The negative explanations *coincide* with a depressed mood, and they are *indicators* of depression. (Before or after being depressed, people's thoughts are less negative. Perhaps a depressed mood triggers negative thoughts.) But do negative thoughts *cause* depression, any more than a speedometer's reading *causes* a car's speed? If you temporarily put people in a bad or sad mood, their memories, judgments, and expectations suddenly become more pessimistic. Memory researchers call this tendency to recall experiences that fit our current good or bad mood *state-dependent memory*.

DEPRESSION'S VICIOUS CYCLE Depression is both a cause and an effect of stressful experiences that disrupt our sense of who we are and why we are worthy human beings. Such disruptions can lead to brooding, which amplifies negative feelings. Being withdrawn, self-focused, and complaining can in turn elicit rejection (Furr & Funder, 1998; Gotlib & Hammen, 1992). Indeed, people in the throes of depression are at high risk for divorce, job loss, and other stressful life events. Weary of the person's fatigue, hopeless attitude, and negativity, a spouse may threaten to leave or a boss may begin to question the person's competence. (This provides another example of genetic-environmental interaction: People genetically predisposed to depression more often experience depressing events.) Rejection and depression feed each other. Misery may love another's company, but company does not love another's misery.

“Man never reasons so much and becomes so introspective as when he suffers, since he is anxious to get at the cause of his sufferings.”

Luigi Pirandello, *Six Characters in Search of an Author*, 1922

“Some cause happiness wherever they go; others, whenever they go.”

Irish writer Oscar Wilde (1854–1900)

We can now assemble some of the pieces of the depression puzzle (**FIGURE 15.9**): (1) Stressful experiences interpreted through (2) a ruminating, pessimistic explanatory style create (3) a hopeless, depressed state that (4) hampers the way the person thinks and acts. This, in turn, fuels (1) further stressful experiences such as rejection. Depression is a snake that bites its own tail.

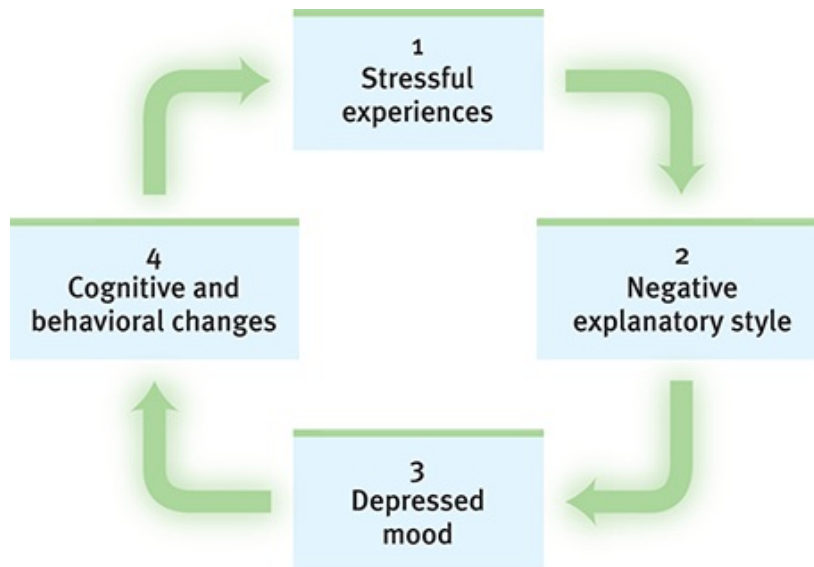

FIGURE 15.9 Myers/DeWall, *Psychology*, 12e,

FIGURE 15.9 The vicious cycle of depressed thinking

Therapists recognize this cycle, and they work to help depressed people break out of it by changing their negative thinking, turning their attention outward, and engaging them in more pleasant and competent behavior.

None of us are immune to the dejection, diminished self-esteem, and negative thinking brought on by rejection or defeat. Even small losses can temporarily sour our thinking. In one study, researchers studied some avid Indiana University basketball fans who seemed to regard the team as an extension of themselves (Hirt et al., 1992). After the fans watched their team lose or win, the researchers asked them to predict the team's future performance and their own. After a loss, the morose fans offered bleaker assessments not only of the team's future but also of their own likely performance at throwing darts, solving anagrams, and getting a date. When things aren't going our way, it may seem as though they never will.

It is a cycle we can all recognize. Bad moods feed on themselves: When we feel down, we think negatively and remember bad experiences. Britain's Prime Minister Winston Churchill called depression a "black dog" that periodically hounded him. Abraham Lincoln was so withdrawn and brooding as a young man that his friends feared he might take his own life (Kline, 1974). Poet Emily Dickinson was so afraid of bursting into tears in public that she spent much of her adult life in seclusion (Patterson, 1951). As their lives remind us, people can and do struggle through depression. Most regain

their capacity to love, to work, and even to succeed at the highest levels.

Suicide and Self-Injury

LOQ 15-13 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

“But life, being weary of these worldly bars,
Never lacks power to dismiss itself.”

William Shakespeare, *Julius Caesar*, 1599

Each year over 800,000 despairing people worldwide will elect a permanent solution to what might have been a temporary problem (WHO, 2014c). For those who have been anxious, the risk of suicide is tripled, and for those who have been depressed, the risk is quintupled (Bostwick & Pankratz, 2000; Kanwar et al., 2013). People seldom commit suicide while in the depths of depression, when energy and initiative are lacking. The risk increases when they begin to rebound and become capable of following through (Chu et al., 2016).

Comparing the suicide rates of different groups, researchers have found

- **national differences:** In Britain, Italy, and Spain, suicide rates have been little more than half those of Canada, Australia, and the United States. Austria’s and Finland’s are about double (WHO, 2011). Within Europe, people in the most suicide-prone country (Belarus) have been 16 times more likely to kill themselves than those in the least (Georgia).
- **racial differences:** Within the United States, Whites and Native Americans kill themselves twice as often as Blacks, Hispanics, and Asians (CDC, 2012).
- **gender differences:** Women are much more likely than men to attempt suicide (WHO, 2011). But men are two to four times more likely (depending on the country) to actually end their lives. Men use more lethal methods, such as firing a bullet into the head, the method of choice in 6 of 10 U.S. suicides.

- ***age differences and trends:*** In late adulthood, rates increase, with the highest rate among 45- to 64-year-olds and the second-highest among those 85 and older (AFSP, 2015). In the last half of the twentieth century, the global rate of annual suicide deaths nearly doubled (WHO, 2008).
- ***other group differences:*** Suicide rates have been much higher among the rich, the nonreligious, and those single, widowed, or divorced (Hoyer & Lund, 1993; Norko et al., 2017; Okada & Samreth, 2013; VanderWeele et al., 2016, 2017). Witnessing physical pain and trauma can increase the risk of suicide, which may help explain veterans' and physicians' elevated suicide rates (Bender et al., 2012; Cornette et al., 2009). Gay, transgender, and gender nonconforming youth facing an unsupportive environment, including family or peer rejection, are also at increased risk of attempting suicide (Goldfried, 2001; Haas et al., 2011; Hatzenbuehler, 2011; Testa et al., 2017). Among people with alcohol use disorder, 3 percent die by suicide. This rate is roughly 100 times greater than the rate for people without alcohol use disorder (Murphy & Wetzel, 1990; Sher, 2006).
- ***day of the week and seasonal differences:*** Negative emotion tends to go up midweek, which can have tragic consequences (Watson, 2000). A surprising 25 percent of U.S. suicides occur on Wednesdays (Kposowa & D'Auria, 2009). Suicide rates are highest in April and May, and not (as commonly believed) over the winter holidays (Nock, 2016).

Social suggestion may trigger suicide. Following highly publicized suicides and TV programs featuring suicide, known suicides increase. So do fatal auto and private airplane “accidents.” One six-year study tracked suicide cases among all 1.2 million people who lived in metropolitan Stockholm at any time during the 1990s (Hedström et al., 2008). Men exposed to a family suicide were 8 times more likely to commit suicide than were nonexposed men. That phenomenon may be partly attributable to family genes. But shared genetic predispositions cannot explain why men exposed to a co-worker's suicide were 3.5 times more likely to commit suicide, compared with nonexposed men.

Suicide is not necessarily an act of hostility or revenge. People—especially older adults—may choose death as an alternative to current or future suffering, a way to switch off unendurable pain and relieve a perceived burden on family members. Suicidal urges typically arise when people feel disconnected from others and a burden to them, or when they feel defeated

and trapped by an inescapable situation (Joiner, 2010; Taylor et al., 2011). Thus, suicide rates increase with unemployment during economic recessions (DeFina & Hannon, 2015; Reeves et al., 2014). Suicidal thoughts also may increase when people are driven to reach a goal or standard—to become thin or straight or rich—and find it unattainable (Chatard & Selimbegović, 2011).

In hindsight, families and friends may recall signs they believe should have forewarned them—verbal hints, giving possessions away, or withdrawal and preoccupation with death. To judge from surveys of 84,850 people across 17 nations, about 9 percent of people at some point in their lives have thought seriously of suicide. About 3 in 10 of those who think about it will actually attempt suicide (Nock et al., 2008). Only 3 percent of Americans die in that attempt (Han et al., 2016). In one study that followed people for up to 25 years after a first suicide attempt, some 5 percent died by suicide (Bostwick et al., 2016). One group of clinical psychologists summarized 50 years of research on suicide's unpredictability: "The vast majority of people who possess a specific risk factor [for suicide] will never engage in suicidal behavior" (Franklin et al., 2017, [p. 217](#)).

But researchers continue to try to solve the suicide puzzle. Although most suicide attempts fail, the risk of death by suicide is seven times greater among those who have previously attempted suicide (Al-Sayegh et al., 2015). Each year, about 40,000 Americans will kill themselves—about two-thirds using guns. (Drug overdoses account for about 80 percent of suicide attempts, but only 14 percent of suicide fatalities.) States with high gun ownership are states with high suicide rates, even after controlling for poverty and urbanization (Miller et al., 2002, 2016; Tavernise, 2013). After Missouri repealed its tough handgun law, its suicide rate went up 15 percent; when Connecticut enacted such a law, its suicide rate dropped 16 percent (Crifasi et al., 2015). Thus, although U.S. gun owners often keep a gun to feel safer, having a gun in the home makes one less safe, because it substantially *increases* the odds of a family member dying by suicide or homicide (Kposowa et al., 2016; VPC, 2015; Vyse, 2016).

How can we be helpful to someone who is talking suicide—who says, for example, "I wish I could just end it all" or "I hate my life; I can't go on"? If people write such things online, you can anonymously contact the safety teams at various social media websites (including Facebook, Twitter, Instagram, YouTube, and Tumblr). If a friend or family member talks

suicide, you can

listen and empathize;

connect the person with your campus counseling center; with (in the United States) the Suicide Prevention Lifeline (1-800-273-TALK) or Crisis Text Line (by texting HOME to 741741); or with their counterparts in other countries (such as the LifeLine App in Canada); and

protect someone who appears at immediate risk by seeking help from a doctor, the nearest hospital emergency room, or 911. Better to share a secret than to attend a funeral.

NONSUICIDAL SELF-INJURY Self-harm takes many forms. Some people may engage in *nonsuicidal self-injury (NSSI)*, which is more common in adolescence and among females (CDC, 2009) ([FIGURE 15.10](#)). Such behavior, though painful, is not fatal. Those who engage in NSSI may cut or burn their skin, hit themselves, insert objects under their nails or skin, or tattoo themselves. People who engage in NSSI tend to experience bullying, harassment, and other life stress (Liu et al., 2016; van Geel et al., 2015). They are generally less able to tolerate and regulate emotional distress (Hamza et al., 2015). They are often extremely self-critical, and struggle to communicate, solve problems, and perform academically (Kiekens et al., 2016; Nock, 2010; You et al., 2015). Why do they hurt themselves? Reinforcement processes are at work (Bentley et al., 2014). Through NSSI they may

FIGURE 15.10 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from CDC, 2009

FIGURE 15.10 Rates of nonfatal self-injury in the United States

Self-injury rates peak higher for females than for males.

- find relief from intense negative thoughts through the distraction of pain.
- attract attention and possibly get help.
- relieve guilt by punishing themselves.
- get others to change their negative behavior (bullying, criticism).
- fit in with a peer group.

Does NSSI lead to suicide? Usually not. Those who engage in NSSI are typically suicide gesturers, not suicide attempters (Nock & Kessler, 2006). Nevertheless, NSSI is a risk factor for suicidal thoughts and future suicide attempts, especially when co-existing with bipolar disorder (Hawton et al., 2015; Runeson et al., 2016; Willoughby et al., 2015). If people do not find help, their nonsuicidal behavior may escalate to suicidal thoughts and, finally, to suicide attempts.

“People desire death when two fundamental needs are frustrated to the point of extinction: The need to belong with or connect to others, and the need to feel effective with or to influence others.”

Thomas Joiner (2006, [p. 47](#))

RETRIEVAL PRACTICE

RP-12 What does it mean to say that “depression is a whole-body disorder”?

ANSWER: Many factors contribute to depression, including the biological influences of genetics and brain function. Social-cognitive factors also matter, including the interaction of explanatory style, mood, our responses to stressful experiences, and changes in our patterns of thinking and behaving. Depression involves the whole body and may disrupt sleep, energy levels, and concentration.

REVIEW Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

LOQ 15-11 [How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?](#)

LOQ 15-12 [How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?](#)

LOQ 15-13 [What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?](#)

TERMS AND CONCEPTS TO REMEMBER

Test yourself on these terms by trying to compose the definition before checking your answers.

[bipolar disorder](#), p. 582

[mania](#), p. 582

[rumination](#), p. 587

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

The gender gap in depression refers to the finding that _____ (men's/women's) risk of depression is nearly double that of _____ (men's/women's).

Rates of bipolar disorder have risen dramatically in the twenty-first century, especially among

- a. middle-aged women.
- b. middle-aged men.
- c. people 20 and over.
- d. people 19 and under.

Treatment for depression often includes drugs that increase supplies of the neurotransmitters _____ and _____.

Psychologists who emphasize the importance of negative perceptions, beliefs, and thoughts in depression are working within the _____ - _____ perspective.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Use  **LearningCurve** to create your personalized study plan, which will direct you to the Macmillan resources that will help you most.

Schizophrenia

During their most severe periods, people with [schizophrenia](#) live in a private inner world, preoccupied with the strange ideas and images that haunt them. The word itself means “split” (*schizo*) “mind” (*phrenia*). It refers *not* to a multiple personality split but rather to the mind’s split from reality. People with schizophrenia have disturbed perceptions and beliefs, disorganized speech, and diminished, inappropriate emotions (and actions). Schizophrenia is the chief example of a [psychotic disorder](#), a group of disorders marked by irrationality, distorted perceptions, and lost contact with reality.

schizophrenia a disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression.

psychotic disorders a group of disorders marked by irrational ideas, distorted perceptions, and a loss of contact with reality.

© Craig Geiser

Art by someone diagnosed with schizophrenia

Commenting on the kind of artwork shown here (from Craig Geiser's 2010 art exhibit in Michigan), poet and art critic John Ashbery wrote: "The lure of the work is strong, but so is the terror of the unanswerable riddles it proposes."

Symptoms of Schizophrenia

LOQ **15-14** What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia comes in varied forms. People with schizophrenia display symptoms that are *positive* (*inappropriate* behaviors are *present*) or negative (*appropriate* behaviors are *absent*). Those with *positive* symptoms may experience hallucinations, talk in disorganized and deluded ways, and exhibit inappropriate laughter, tears, or rage. Those with *negative* symptoms may have toneless voices, expressionless faces, or mute and rigid bodies.

DISTURBED PERCEPTIONS AND BELIEFS People with schizophrenia sometimes have *hallucinations*—they see, feel, taste, or smell things that exist only in their minds. Most often, the hallucinations are voices, which sometimes make insulting remarks or give orders. The voices may tell the person that she is bad or that she must burn herself with a cigarette lighter. Imagine your own reaction if a dream broke into your waking consciousness, making it hard to separate your experience from your imagination. When the unreal seems real, the resulting perceptions are at best bizarre, at worst terrifying.

Hallucinations are false *perceptions*. People with schizophrenia also have disorganized, fragmented thinking, often distorted by false *beliefs* called **delusions**. If they have *paranoid* tendencies, they may believe they are being threatened or pursued.

delusion a false belief, often of persecution or grandeur, that may accompany psychotic disorders.

One cause of disorganized thinking may be a breakdown in *selective*

attention. Normally, we have a remarkable capacity to give our undivided attention to one set of sensory stimuli while filtering out others. People with schizophrenia are easily distracted by tiny unrelated stimuli, such as the grooves on a brick or tones in a voice. This selective attention difficulty is but one of dozens of cognitive differences associated with schizophrenia (Reichenberg & Harvey, 2007).

“Now consider this: The regulator that funnels certain information to you and filters out other information suddenly shuts off. Immediately, every sight, every sound, every smell coming at you carries equal weight; every thought, feeling, memory, and idea presents itself to you with an equally strong and demanding intensity.”

Elyn R. Saks, *The Center Cannot Hold*, 2007

DISORGANIZED SPEECH Maxine, a young woman with schizophrenia, believed she was Mary Poppins. Communicating with Maxine was difficult because her thoughts spilled out in no logical order. Her biographer, Susan Sheehan (1982, [p. 25](#)), observed her saying aloud to no one in particular, “This morning, when I was at Hillside [Hospital], I was making a movie. I was surrounded by movie stars. . . . Is this room painted blue to get me upset? My grandmother died four weeks after my eighteenth birthday.”

Jumbled ideas may make no sense even within sentences, forming what is known as *word salad*. One young man begged for “a little more allegro in the treatment,” and suggested that “liberationary movement with a view to the widening of the horizon” will “ergo extort some wit in lectures.”

DIMINISHED AND INAPPROPRIATE EMOTIONS The expressed emotions of schizophrenia are often utterly inappropriate, split off from reality (Kring & Caponigro, 2010). Maxine laughed after recalling her grandmother’s death. On other occasions, she cried when others laughed, or became angry for no apparent reason. Others with schizophrenia lapse into an emotionless *flat affect* state of no apparent feeling. For example, monetary perks fail to provide the normal brain reward center activation (Radua et al., 2015). Most also have an *impaired theory of mind*—they have difficulty perceiving facial expressions and reading others’ states of mind (Bora & Pantelis, 2016). Unable to understand others’ mental states, those with

schizophrenia struggle to feel sympathy and compassion (Bonfils et al., 2016). These emotional deficiencies occur early in the illness and have a genetic basis (Bora & Pantelis, 2013). Motor behavior may also be inappropriate and disruptive. Those with schizophrenia may experience *catatonia*, characterized by motor behaviors ranging from a physical stupor—remaining motionless for hours—to senseless, compulsive actions, such as continually rocking or rubbing an arm, to severe and dangerous agitation.

As you can imagine, such disturbed perceptions and beliefs, disorganized speech, and out of place emotions profoundly disrupt social and work relationships. During their most severe periods, people with schizophrenia live in a private inner world, preoccupied with illogical ideas and unreal images. As with other disorders, many have sleep problems, which can increase night eating and obesity (Baglioni et al., 2016; Palmese et al., 2011). Given a supportive environment and medication, over 40 percent of people with schizophrenia will have periods of a year or more of normal life experience (Jobe & Harrow, 2010). But only 1 in 7 will have a full and enduring recovery (Jääskeläinen et al., 2013).

Onset and Development of Schizophrenia

LOQ **15-15** How do *chronic schizophrenia* and *acute schizophrenia* differ?

This year, 1 in 100 people will join an estimated 21 million others worldwide who have schizophrenia (WHO, 2017a). This disorder knows no national boundaries and it typically strikes as young people are maturing into adulthood. Men tend to be struck earlier, more severely, and more often (Aleman et al., 2003; Eranti et al., 2013; Picchioni & Murray, 2007).

When schizophrenia is a slow-developing process, called **chronic schizophrenia**, recovery is doubtful (Harrison et al., 2001; Jääskeläinen et al., 2013). This was the case with Maxine, whose schizophrenia took a slow course, emerging from a long history of social inadequacy and poor school performance (MacCabe et al., 2008). Social withdrawal, a negative symptom, is often found among those with chronic schizophrenia (Kirkpatrick et al., 2006). Men, whose schizophrenia develops on average four years earlier than women's, more often exhibit negative symptoms and chronic schizophrenia

(Räsänen et al., 2000).

chronic schizophrenia (also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As people age, psychotic episodes last longer and recovery periods shorten.

When previously well-adjusted people develop schizophrenia rapidly following particular life stresses, this is called **acute schizophrenia**, and recovery is much more likely. They more often have positive symptoms that respond to drug therapy (Fenton & McGlashan, 1991, 1994; Fowles, 1992).

acute schizophrenia (also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age, frequently occurs in response to an emotionally traumatic event, and has extended recovery periods.

Understanding Schizophrenia

Schizophrenia is one of the most heavily researched psychological disorders. Most studies now link it with abnormal brain tissue and genetic predispositions. Schizophrenia is a disease of the brain manifested in symptoms of the mind.

Brain Abnormalities

LOQ **15-16** What brain abnormalities are associated with schizophrenia?

Might chemical imbalances in the brain underlie schizophrenia? Scientists have long known that strange behavior can have strange chemical causes. The saying “mad as a hatter” is often thought to refer to the psychological deterioration of British hat makers whose brains, it was later discovered, were slowly poisoned by the mercury-laden felt material (Smith, 1983). Could

schizophrenia symptoms have a similar biochemical key? Scientists are searching for blood proteins that might predict schizophrenia onset (Chan et al., 2015). And they are tracking the mechanisms by which chemicals produce hallucinations and other symptoms.

DOPAMINE OVERACTIVITY One possible answer emerged when researchers examined schizophrenia patients' brains after death. They found an excess number of *dopamine* receptors, including a sixfold excess for the dopamine receptor D4 (Seeman et al., 1993; Wong et al., 1986). Such a hyper-responsive dopamine system may intensify brain signals in schizophrenia, creating positive symptoms such as hallucinations and paranoia (Maia & Frank, 2017). Drugs that block dopamine receptors often lessen these symptoms. Drugs that increase dopamine levels, such as amphetamines and cocaine, sometimes intensify them (Basu & Basu, 2015; Farnia et al., 2014).

Most people with schizophrenia smoke, which both increases their vulnerability to schizophrenia and contributes to their having a 14.5 year shorter-than-average life expectancy (Gurillo et al., 2015; Hjorthøj et al., 2017; Kendler et al., 2015b; Olfson et al., 2015).

ABNORMAL BRAIN ACTIVITY AND ANATOMY Abnormal brain activity and brain structures accompany schizophrenia. Some people diagnosed with schizophrenia have abnormally low brain activity in the frontal lobes, areas that help us reason, plan, and solve problems (Morey et al., 2005; Pettegrew et al., 1993; Resnick, 1992). Brain scans also show a noticeable decline in the brain waves that reflect synchronized neural firing in the frontal lobes (Spencer et al., 2004; Symond et al., 2005).

One study took PET scans of brain activity while people were hallucinating (Sil-bersweig et al., 1995). When participants heard a voice or saw something, their brain became vigorously active in several core regions. One was the thalamus, the structure that filters incoming sensory signals and transmits them to the brain's cortex. Another PET scan study of people with paranoia found increased activity in the amygdala, a fear-processing center (Epstein et al., 1998).

Many studies have also found enlarged, fluid-filled ventricles and a

corresponding shrinkage and thinning of cerebral tissue (Goldman et al., 2009; van Haren et al., 2016). People often inherit these brain differences. If one affected identical twin shows brain abnormalities, the odds are at least 1 in 2 that the other twin's brain will have them (van Haren et al., 2012). Some studies have even found these abnormalities in people who *later* developed the disorder (Karlsgodt et al., 2010). The greater the brain shrinkage, the more severe the thought disorder (Collinson et al., 2003; Nelson et al., 1998; Shenton, 1992).

Smaller-than-normal areas may include the cortex, the hippocampus, and the corpus callosum connecting the brain's two hemispheres (Arnone et al., 2008; Bois et al., 2016). Another is the thalamus, which may explain why people with schizophrenia have difficulty filtering sensory input and focusing attention (Andreasen et al., 1994; Ellison-Wright et al., 2008). Schizophrenia also tends to involve a loss of neural connections across the brain network (Bohlken et al., 2016; Kambeitz et al., 2016). *The bottom line:* Schizophrenia involves not one isolated brain abnormality but problems with several brain regions and their interconnections (Andreasen, 1997, 2001; Arnedo et al., 2015).

Prenatal Environment and Risk

LOQ **15-17** What prenatal events are associated with increased risk of developing schizophrenia?

What causes brain abnormalities in people with schizophrenia? Some scientists point to mishaps during prenatal development or delivery (Fatemi & Folsom, 2009; Walker et al., 2010). Risk factors include low birth weight, maternal diabetes, older paternal age, and oxygen deprivation during delivery (King et al., 2010). Famine may also increase risks. People conceived during the peak of World War II's Dutch wartime famine later developed schizophrenia at twice the normal rate. Those conceived during the famine of 1959 to 1961 in eastern China also displayed this doubled rate (St. Clair et al., 2005; Susser et al., 1996).

Let's consider another possible culprit. Might a midpregnancy viral infection impair fetal brain development (Brown & Patterson, 2011)? Can you imagine some ways to test this fetal-virus idea? Scientists have asked the following:

- *Are people at increased risk of schizophrenia if, during the middle of their fetal development, their country experienced a flu epidemic?* The repeated answer has been Yes (Mednick et al., 1994; Murray et al., 1992; Wright et al., 1995).
- *Are people born in densely populated areas, where viral diseases spread more readily, at greater risk for schizophrenia?* The answer, confirmed in a study of 1.75 million Danes, has again been Yes (Jablensky, 1999; Mortensen, 1999).
- *Are those born during the winter and spring months—those who were in utero during the fall-winter flu season—also at increased risk?* Although the increase is small, just 5 to 8 percent, the answer has been Yes (Fox, 2010; Schwartz, 2011; Torrey & Miller, 2002; Torrey et al., 1997).
- *In the Southern Hemisphere, where the seasons are the reverse of the Northern Hemisphere, are the months of above-average pre-schizophrenia births similarly reversed?* Again, the answer has been Yes. In Australia, people born between August and October are at greater risk. But people born in the Northern Hemisphere who later moved to Australia still have a greater risk if they were born between January and March (McGrath et al., 1995; McGrath & Welham, 1999).
- *Are mothers who report being sick with influenza during pregnancy more likely to bear children who develop schizophrenia?* In one study of nearly 8000 women, the answer was Yes. The schizophrenia risk increased from the customary 1 percent to about 2 percent—but only when infections occurred during the second trimester (Brown et al., 2000). Maternal influenza infection during pregnancy affects brain development in monkeys as well (Short et al., 2010).
- *Does blood drawn from pregnant women whose offspring develop schizophrenia show higher-than-normal levels of antibodies that suggest a viral infection?* In several studies—including one that collected blood samples from some 20,000 pregnant women—the answer has again been Yes (Brown et al., 2004; Buka et al., 2001; Canetta et al., 2014).

These converging lines of evidence suggest that fetal-virus infections contribute to the development of schizophrenia. They also strengthen the U.S. government recommendation that “pregnant women need a flu shot” (CDC, 2014b).

Genetic Factors

LOQ 15-18 How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Fetal-virus infections may increase the odds that a child will develop schizophrenia. But many women get the flu during their second trimester of pregnancy, and only 2 percent of them bear children who develop schizophrenia. Why are only some children at risk? Might some people be more genetically vulnerable to schizophrenia? Yes. The 1-in-100 odds of any person's being diagnosed with schizophrenia become about 1 in 10 among those who have a sibling or parent with the disorder. If the affected sibling is an identical twin, the odds increase to nearly 1 in 2 ([FIGURE 15.11](#)). Those odds remain the same even when the twins are raised apart (Plomin et al., 1997). (Only about a dozen such cases are on record.)

FIGURE 15.11 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Gottesman, 2001

FIGURE 15.11 Risk of developing schizophrenia

The lifetime risk of developing schizophrenia varies with one's genetic relatedness to someone having this disorder. Across countries, barely more than 1 in 10 fraternal twins, but some 5 in 10 identical twins, share a schizophrenia diagnosis.

See the **Video: Twin Studies** for a helpful tutorial animation about this type of research design.

Remember, though, that identical twins share more than their genes. They also share a prenatal environment. About two-thirds share a placenta and the blood it supplies; the other third have separate placentas. Shared placentas

matter. If the co-twin of an identical twin with schizophrenia shared the placenta, the chances of developing the disorder are 6 in 10. If the identical twins had separate placentas, the co-twin's chances of developing schizophrenia drop to 1 in 10 (Davis et al., 1995; Davis & Phelps, 1995; Phelps et al., 1997). Twins who share a placenta are more likely to share the same prenatal viruses. So perhaps shared germs as well as shared genes produce identical twin similarities.

Adoption studies help untangle genetic and environmental influences. Children adopted by someone who develops schizophrenia do not “catch” the disorder. Rather, adopted children have an elevated risk if a *biological* parent is diagnosed with schizophrenia (Gottesman, 1991). Genes matter.

The search is on for specific genes that, in some combination, predispose schizophrenia-inducing brain abnormalities ([FIGURE 15.12](#)). (It is not our genes but our brains that directly control our behavior.) In the biggest-ever study of the genetics of psychiatric disorder, scientists from 35 countries pooled data from the genomes of 37,000 people with schizophrenia and 113,000 people without (Schizophrenia Working Group, 2014). They found 103 genome locations linked with this disorder. Some genes influence the effects of dopamine and other neurotransmitters in the brain. Others affect the production of *myelin*, a fatty substance that coats the axons of nerve cells and lets impulses travel at high speed through neural networks.

FIGURE 15.12 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
From Daniel Weinberger, M.D., CBDB, NIMH

FIGURE 15.12 Schizophrenia in identical twins

When twins differ, only the one afflicted with schizophrenia typically has

enlarged, fluid-filled cranial cavities (right) (Suddath et al., 1990). The difference between the twins implies some nongenetic factor, such as a virus, is also at work.

Although genes matter, the genetic formula is not as straightforward as the inheritance of eye color. Schizophrenia is a group of disorders influenced by many genes, each with very small effects (Arnedo et al., 2015; Darby et al., 2016; International Schizophrenia Consortium, 2009). And, as we have so often seen, nature and nurture interact. *Epigenetic* factors influence whether genes will be expressed. Like hot water activating a tea bag, environmental factors such as viral infections, nutritional deprivation, and maternal stress can “turn on” the genes that put some of us at higher risk for schizophrenia. Identical twins’ differing histories in the womb and beyond explain why they may show differing gene expressions (Dempster et al., 2013; Walker et al., 2010). Our heredity and our life experiences work together. Neither hand claps alone.

Thanks to our expanding understanding of genetic and brain influences on maladies such as schizophrenia, the general public more and more attributes psychiatric disorders to biological factors (Pescosolido et al., 2010). So, will scientists develop genetic tests that reveal who is at risk? If so, will people in the future subject their embryos to genetic testing (and gene repair or abortion) if they are at risk for this or some other psychological or physical malady? Might they take their egg and sperm to a genetics lab for screening before combining them to produce an embryo? Or will children be tested for genetic risks and given appropriate preventive treatments? In this brave new twenty-first-century world, such questions await answers.

Consider how researchers have studied these issues by engaging online with **Immersive Learning: How Would You Know If Schizophrenia Is Inherited?**

Environmental Triggers for Schizophrenia

If prenatal viruses and genetic predispositions do not, by themselves, cause schizophrenia, neither do family or social factors alone. It remains true, as Susan Nicol and Irving Gottesman (1983) noted over three decades ago, that “no environmental causes have been discovered that will invariably, or even

with moderate probability, produce schizophrenia in persons who are not related to” a person with schizophrenia.

Hoping to identify environmental triggers of schizophrenia, researchers have compared the experiences of high-risk children (for example, those with relatives with schizophrenia) and low-risk children. In one 2.5-year study that followed 163 teens and early-twenties adults who had two relatives with schizophrenia, the 20 percent of participants who developed schizophrenia showed social withdrawal or other abnormal behavior before the onset of the disorder (Johnstone et al., 2005). Researchers identified other possible early warning signs, including a mother whose schizophrenia was severe and long-lasting; birth complications (often involving oxygen deprivation and low birth weight); separation from parents; short attention span and poor muscle coordination; disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play; and childhood physical, sexual, or emotional abuse (Abel et al., 2010; Freedman et al., 1998; Schiffman et al., 2001; Susser, 1999; Welham et al., 2009).

* * *

Few of us can relate to the strange thoughts, perceptions, and behaviors of schizophrenia. Sometimes our thoughts jump around, but we rarely talk nonsensically. Occasionally we feel unjustly suspicious of someone, but we do not fear that the world is plotting against us. Often our perceptions err, but rarely do we see or hear things that are not there. We feel regret after laughing at someone’s misfortune, but we rarely giggle in response to our own bad news. At times we just want to be alone, but we do not live in social isolation. However, millions of people around the world do talk strangely, suffer delusions, hear nonexistent voices, see things that are not there, laugh or cry at inappropriate times, or withdraw into private imaginary worlds. The quest to solve the cruel puzzle of schizophrenia continues, more vigorously than ever.

RETRIEVAL PRACTICE

RP-13 A person with schizophrenia who has _____
(positive/negative) symptoms may have an expressionless
face and toneless voice. These symptoms are most

common with _____ (chronic/acute) schizophrenia and are not likely to respond to drug therapy. Those with _____ (positive/negative) symptoms are likely to experience delusions and to be diagnosed with _____ (chronic/acute) schizophrenia, which is much more likely to respond to drug therapy.

ANSWER: negative; chronic; positive; acute.

RP-14 What factors contribute to the onset and development of schizophrenia?

ANSWER: Biological factors include abnormalities in brain structure and function and a genetic predisposition to the disorder. Environmental factors such as nutritional deprivation, exposure to virus, and maternal stress contribute by activating the genes that increase risk. Exposure to many environmental triggers can increase the odds of developing schizophrenia.

For an 8-minute description of how clinicians define and treat schizophrenia, see the **Video: Schizophrenia–New Definitions, New Therapies**.

REVIEW **Schizophrenia**

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Victor exclaimed, "The weather has been so schizophrenic lately: It's hot one day and freezing the next!" Is this an accurate comparison? Why or why not?

A person with positive symptoms of schizophrenia is most likely to experience

a. catatonia.

- b. delusions.
- c. withdrawal.
- d. flat emotion.

People with schizophrenia may hear voices urging self-destruction, an example of a(n) _____.

Chances for recovery from schizophrenia are best when

- a. onset is sudden, in response to stress.
- b. deterioration occurs gradually, during childhood.
- c. no environmental causes can be identified.
- d. there is a detectable brain abnormality.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Dissociative, Personality, and Eating Disorders

Dissociative Disorders

LOQ **15-19** What are *dissociative disorders*, and why are they controversial?

Among the most bewildering disorders are the rare **dissociative disorders**, in which a person's conscious awareness *dissociates* (separates) from painful memories, thoughts, and feelings. The result may be a *fugue state*, a sudden loss of memory or change in identity, often in response to an overwhelmingly stressful situation. Such was the case for one Vietnam veteran who was haunted by his comrades' deaths, and who had left his World Trade Center office shortly before the 9/11 terrorist attack. Later, he disappeared. Six months later, when he was discovered in a Chicago homeless shelter, he reported no memory of his identity or family (Stone, 2006).

dissociative disorders controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings.

Dissociation itself is not so rare. Any one of us may have a sense of being unreal, of being separated from our body, of watching ourselves as if in a movie. Sometimes we may say, "I was not myself at the time." Perhaps you can recall getting up to go somewhere and ending up at some unintended location while your mind was preoccupied. Or perhaps you can play a well-practiced tune on a guitar or piano while talking to someone. When we face trauma, dissociative detachment may protect us from being overwhelmed by emotion.

Dissociative Identity Disorder

A massive dissociation of self from ordinary consciousness occurs in dissociative identity disorder (**DID**—formerly called *multiple personality disorder*), in which two or more distinct identities—each with its own voice and mannerisms—seem to control a person’s behavior at different times. Thus, the person may be prim and proper one moment, loud and flirtatious the next. Typically, the original personality denies any awareness of the other(s).

dissociative identity disorder (DID) a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. (Formerly called *multiple personality disorder*.)

Multiple personalities Chris Sizemore’s story, told in the book and movie *The Three Faces of Eve*, gave early visibility to what is now called *dissociative identity disorder*.

People diagnosed with DID are rarely violent. But cases have been reported of dissociations into a “good” and a “bad” (or aggressive) personality—a modest version of the Dr. Jekyll–Mr. Hyde split immortalized in Robert Louis Stevenson’s story. One unusual case involved Kenneth Bianchi, accused in the “Hillside Strangler” rapes and murders of 10 California women. During a hypnosis session, Bianchi’s psychologist “called forth” a hidden personality: “I’ve talked a bit to Ken, but I think that perhaps

there might be another part of Ken that . . . maybe feels somewhat differently from the part that I've talked to. . . . Would you talk with me, Part, by saying, 'I'm here'?" Bianchi answered "Yes" and then claimed to be "Steve" (Watkins, 1984).

Speaking as Steve, Bianchi stated that he hated Ken because Ken was nice and that he (Steve), aided by a cousin, had murdered women. He also claimed Ken knew nothing about Steve's existence and was innocent of the murders. Was Bianchi's second personality a trick, simply a way of disavowing responsibility for his actions? Indeed, Bianchi—a practiced liar who had read about multiple personality in psychology books—was later convicted.

Understanding Dissociative Identity Disorder

Skeptics question DID. First, instead of being a true disorder, could DID be an extension of our normal capacity for personality shifts? Nicholas Spanos (1986, 1994, 1996) asked college students to pretend they were accused murderers being examined by a psychiatrist. Given the same hypnotic treatment Bianchi received, most spontaneously expressed a second personality. This discovery made Spanos wonder: Perhaps dissociative identities are simply a more extreme version of the varied "selves" we normally present—as when we display a goofy, loud self while hanging out with friends, and a subdued, respectful self around grandparents. Are clinicians who discover multiple personalities merely triggering role playing by fantasy-prone people? Do these people, like actors who commonly report "losing themselves" in their roles, then convince themselves of the authenticity of their own role enactments? Spanos was no stranger to this line of thinking. In a related research area, he had also raised these questions about the hypnotic state. Because most DID patients are highly hypnotizable, whatever explains one condition—dissociation or role playing—may help explain the other.

"Pretense may become reality."

Chinese proverb

Skeptics also find it suspicious that the disorder has such a short and

localized history. Between 1930 and 1960, the number of North American DID diagnoses averaged 2 per decade. By the 1980s, when the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM) contained the first formal code for this disorder, the number had exploded to more than 20,000 (McHugh, 1995a). The average number of displayed personalities also mushroomed—from 3 to 12 per patient (Goff & Simms, 1993). Although diagnoses are increasing in countries where DID has been publicized, the disorder is much less prevalent outside North America (Lilienfeld, 2017). In Britain, DID—which some have considered “a wacky American fad” (Cohen, 1995)—has been rare.

Such findings, skeptics have noted, point to a disorder of suggestible, fantasy-prone people created by therapists in a particular social context (Giesbrecht et al., 2008, 2010; Lynn et al., 2014; Merskey, 1992). Clients do not enter therapy saying “Allow me to introduce myself.” Instead, charge the critics, some therapists go fishing for multiple personalities: “*Have you ever felt like another part of you does things you can't control? Does this part of you have a name? Can I talk to the angry part of you?*” Once clients permit a therapist to talk, by name, “to the part of you that says those angry things,” they begin acting out the fantasy. The result may be the experience of another self.

Other researchers and clinicians believe DID is a real disorder. They cite findings of distinct body and brain states associated with differing personalities (Putnam, 1991). Abnormal brain anatomy and activity can also accompany DID. Brain scans show shrinkage in areas that aid memory and detection of threat (Vermetten et al., 2006). Heightened activity appears in brain areas associated with the control and inhibition of traumatic memories (Elzinga et al., 2007).

The Mankato Free Press/AP Photo

Widespread dissociation

Shirley Mason was a psychiatric patient diagnosed with dissociative identity disorder. Her life formed the basis of the bestselling book, *Sybil* (Schreiber, 1973), and of two movies. Some argue that the book and movies' popularity fueled the dramatic rise in diagnoses of DID. Skeptics wonder whether Mason actually had the disorder (Nathan, 2011).

Both the psychodynamic and learning perspectives have interpreted DID symptoms as ways of coping with anxiety. Some psychodynamic theorists see them as defenses against the anxiety caused by the eruption of unacceptable impulses. In this view, a second personality enables the discharge of forbidden impulses. Learning theorists see dissociative disorders as behaviors reinforced by anxiety reduction.

“Though this be madness, yet there is method in ‘t.”

William Shakespeare, *Hamlet*, 1600

Some clinicians include dissociative disorders under the umbrella of posttraumatic stress disorder—a natural, protective response to traumatic experiences during childhood (Brand et al., 2016; Spiegel, 2008). Many

people being treated for DID recall being physically, sexually, or emotionally abused as children (Gleaves, 1996; Lilienfeld et al., 1999). In one study of 12 murderers diagnosed with DID, 11 had suffered severe, torturous child abuse (Lewis et al., 1997). One had been set afire by his parents. Another had been used in child pornography and was scarred from being made to sit on a stove burner. Some critics wonder, however, whether vivid imagination or therapist suggestion contributed to such recollections (Kihlstrom, 2005).

So the debate continues. On one side are those who believe multiple personalities are the desperate efforts of people trying to detach from a horrific existence. On the other are skeptics who think DID is constructed out of the therapist-client interaction and acted out by fantasy-prone, emotionally vulnerable people. If the skeptics' view wins, predicted psychiatrist Paul McHugh (1995b), "this epidemic will end in the way that the witch craze ended in Salem. The [multiple personality phenomenon] will be seen as manufactured."

Leo Cullum The New Yorker Collection/
The Cartoon Bank

"Would it be possible to speak with the personality that pays the bills?"

RETRIEVAL PRACTICE

RP-15 The psychodynamic and learning perspectives agree that dissociative identity disorder symptoms are ways of dealing with anxiety. How do their explanations differ?

ANSWER: The psychodynamic explanation of DID symptoms is that they are defenses against anxiety generated by

unacceptable urges. The learning perspective attempts to explain these symptoms as behaviors that have been reinforced by relieving anxiety.

Personality Disorders

LOQ **15-20** What are the three clusters of personality disorders?

What behaviors and brain activity characterize the antisocial personality?

The inflexible and enduring behavior patterns of [personality disorders](#) interfere with social functioning. The ten disorders in DSM-5 tend to form three clusters, characterized by

personality disorders inflexible and enduring behavior patterns that impair social functioning.

- anxiety, such as a fearful sensitivity to rejection that predisposes the withdrawn *avoidant personality disorder*.
- eccentric or odd behaviors, such as the emotionless disengagement of *schizotypal personality disorder*.
- dramatic or impulsive behaviors, such as the attention-getting *borderline personality disorder*, the self-focused and self-inflating *narcissistic personality disorder*, and—what we next discuss as an in-depth example—the callous, and often dangerous, *antisocial personality disorder*.

JEFF TUTTLE/Tribune News Service/Newscom

No remorse

Dennis Rader, known as the “BTK killer” in Kansas, was convicted in 2005 of killing 10 people over a 30-year span. Rader exhibited the extreme lack of conscience that marks antisocial personality disorder.

Antisocial Personality Disorder

People with [antisocial personality disorder](#), usually male, can display symptoms by age 8. Their lack of conscience becomes plain before age 15, as they begin to lie, steal, fight, or display unrestrained sexual behavior (Cale & Lilienfeld, 2002). Not all children with these traits become antisocial adults. (Note: “Antisocial” means disruptive, not just unsociable.) Those who do (about half of them) will generally act in violent or otherwise criminal ways, be unable to keep a job, and, if they have a spouse or children, behave irresponsibly toward them (Farrington, 1991). People with antisocial personality disorder (sometimes called *sociopaths* or *psychopaths*) may show lower *emotional intelligence*—the ability to understand, manage, and perceive emotions (Ermer et al., 2012).

antisocial personality disorder a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist.

Despite their remorseless and sometimes criminal behavior, criminality is not an essential component of antisocial behavior (Skeem & Cooke, 2010). Moreover, many criminals do not fit the description of antisocial personality disorder. Why? Because they're not impulsive (Geurts et al., 2016). Rather, they actually show responsible concern for their friends and family members. When the antisocial personality combines a keen intelligence with amorality, the result may be a charming and clever con artist—or a fearless, focused, ruthless soldier, surgeon, or CEO (Dutton, 2012; Schütte et al., 2016).

Antisocial personalities behave impulsively, and then feel and fear little (Fowles & Dindo, 2009). Their impulsivity can have horrific consequences (Camp et al., 2013). Consider the case of Henry Lee Lucas. He killed his first victim when he was 13. He felt little regret then or later. During his years of crime, he brutally murdered 157 women, men, and children. For the last six years of his reign of terror, Lucas teamed with Ottis Elwood Toole, who reportedly slaughtered people he “didn’t think was worth living anyhow” (Darrach & Norris, 1984).

Understanding Antisocial Personality Disorder

Antisocial personality disorder is woven of both biological and psychological strands. Twin and adoption studies reveal that biological relatives of people with antisocial and unemotional tendencies are at increased risk for antisocial behavior (Frisell et al., 2012; Kendler et al., 2015b). People with antisocial personalities sometimes spread their genes to future generations by marrying others who have antisocial personalities (Weiss et al., 2017). No single gene codes for a complex behavior such as crime. Molecular geneticists have, however, identified some specific genes that are more common in those with antisocial personality disorder (Gunter et al., 2010).

"Thursday is out. I have jury duty."

Leo Cullum The New Yorker Collection/
The Cartoon Bank

Many criminals, like the one above, exhibit a sense of conscience and responsibility in other areas of their life, and thus do not exhibit antisocial personality disorder.

The genetic vulnerability of people with antisocial and unemotional tendencies appears as low arousal in response to threats. Awaiting aversive events, such as electric shocks or loud noises, they show little autonomic nervous system arousal (Hare, 1975; Hoppenbrouwers et al., 2016). Long-term studies show that their stress hormone levels were lower than average as teenagers, before committing any crime ([FIGURE 15.13](#)). And those who were slow to develop conditioned fears at age 3 were also more likely to commit a crime later in life (Gao et al., 2010). Other studies have found that preschool boys who later became aggressive or antisocial adolescents tended to be impulsive, uninhibited, unconcerned with social rewards, and low in anxiety (Caspi et al., 1996; Tremblay et al., 1994).

FIGURE 15.13 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers
Data from Magnusson, 1990

FIGURE 15.13 Cold-blooded arousability and risk of crime

Levels of the stress hormone adrenaline were measured in two groups of 13-year-old Swedish boys. In both stressful and nonstressful situations, those who would later be convicted of a crime as 18- to 26-year-olds showed relatively low arousal. (Data from Magnusson, 1990.)

Traits such as fearlessness and dominance can be adaptive. If channeled in more productive directions, fearlessness may lead to athletic stardom, adventurism, or courageous heroism (Smith et al., 2013). In one analysis, 42 American presidents scored higher than the general population on such traits as fearlessness and dominance (Lilienfeld et al., 2012, 2016). Patient S. M., a 49-year-old woman who experienced damage to her amygdala, showed fearlessness and impulsivity but also displayed acts of heroism (Lilienfeld et al., 2017). For example, she gave a man in need her only coat and scarf. Befriending a child with cancer, how did she respond? She cut her hair short and donated it to the Locks of Love charity.

Genetic influences, often in combination with negative environmental factors such as childhood abuse, family instability, or poverty, help wire the brain (Dodge, 2009). In people with antisocial criminal tendencies, the emotion-controlling amygdala is smaller (Pardini et al., 2014). The frontal lobes are also less active, as Adrian Raine (1999, 2005) found when he compared PET scans of 41 murderers' brains with those from people of similar age and sex ([FIGURE 15.14](#)). The frontal lobes help control impulses. The reduced activation was especially apparent in those who murdered

impulsively. In a follow-up study, Raine and his team (2000) found that violent repeat offenders had 11 percent less frontal lobe tissue than normal. This helps explain why people with antisocial personality disorder exhibit marked deficits in frontal lobe cognitive functions, such as planning, organization, and inhibition (Morgan & Lilienfeld, 2000). Compared with people who feel and display empathy, their brains also respond less to facial displays of others' distress, which may contribute to their lower emotional intelligence (Deeley et al., 2006).

FIGURE 15.14 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

FIGURE 15.14 Murderous minds

Researchers have found reduced activation in a murderer's frontal lobes. This brain area (shown in a left-facing brain) helps brake impulsive, aggressive behavior (Raine, 1999).

A biologically based fearlessness, as well as early environment, helps explain an unusual family reunion. Long-separated sisters Joyce Lott, 27, and Mary Jones, 29, came together at a place that normally separates family members rather than brings them together—a South Carolina prison where both were sent on drug charges. After a newspaper story about their reunion, their long-lost half-brother Frank Strickland called. But he had his own problem: He was stuck in jail on drug, burglary, and larceny charges (Shepherd et al., 1990). The genes that put people at risk for antisocial behavior also put people at risk for substance use disorders, which may help explain why these disorders often appear in combination (Dick, 2007).

Genetics alone do not tell the whole story of antisocial crime, however. In

another Raine-led study (1996), researchers checked criminal records on nearly 400 Danish men at ages 20 to 22. All these men either had experienced biological risk factors at birth (such as premature birth) or came from family backgrounds marked by poverty and family instability. The researchers then compared each of these two groups with a third *biosocial* group (people whose lives were marked by *both* those biological and social risk factors). The biosocial group had double the risk of committing crime. Similar findings emerged from a famous study that followed 1037 children for a quarter-century: Two combined factors—childhood maltreatment and a gene that altered neurotransmitter balance—predicted antisocial problems (Caspi et al., 2002). Neither “bad” genes alone nor a “bad” environment alone predisposed later antisocial behavior. Rather, genes predisposed some children to be more sensitive to maltreatment. Within “genetically vulnerable segments of the population,” environmental influences matter—for better or for worse (Belsky & Pluess, 2009; Moffitt, 2005).

Does a full Moon trigger “madness” in some people? Researchers examined data from 37 studies that related lunar phase to crime, homicides, crisis calls, and psychiatric hospital admissions (Rotton & Kelley, 1985). Their conclusion: There is virtually no evidence of “Moon madness.” Nor does lunar phase correlate with suicides, assaults, emergency room visits, or traffic disasters (Martin et al., 1992; Raison et al., 1999).

With antisocial behavior, as with so much else, nature and nurture interact and the biopsychosocial perspective helps us understand the whole story. To explore the neural basis of antisocial personality disorder, neuroscientists are trying to identify brain activity differences in criminals who display symptoms of this disorder. Shown emotionally evocative photographs, such as a man holding a knife to a woman’s throat, criminals with antisocial personality disorder display blunted heart rate and perspiration responses, and less activity in brain areas that typically respond to emotional stimuli (Harenski et al., 2010; Kiehl & Buckholtz, 2010). They also have a larger and hyper-reactive dopamine reward system, which predisposes their impulsive drive to do something rewarding despite the consequences (Buckholtz et al., 2010; Glenn et al., 2010). Such data provide another reminder: Everything

psychological is also biological.

RETRIEVAL PRACTICE

RP-16 How do biological and psychological factors contribute to antisocial personality disorder?

ANSWER: Twin and adoption studies show that biological relatives of people with this disorder are at increased risk for antisocial behavior. Researchers have also observed differences in the brain activity and structure of antisocial criminals. Negative environmental factors, such as poverty or childhood abuse, may channel genetic traits such as fearlessness in more dangerous directions—toward aggression and away from social responsibility.

© Nick Holt Photography

Sibling rivalry gone awry

Twins Maria and Katy Campbell have anorexia nervosa. As children they competed to see who could be thinner. Now, says Maria, her anorexia nervosa is “like a ball and chain around my ankle that I can’t throw off” (Foster, 2011).

Eating Disorders

LOQ 15-21 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

Our bodies are naturally disposed to maintain a steady weight, including stored energy reserves for times when food becomes unavailable. But sometimes psychological influences overwhelm biological wisdom. This becomes painfully clear in three eating disorders.

- [Anorexia nervosa](#) typically begins as a weight-loss diet. People with anorexia—usually female adolescents, but some women, men, and boys as well—drop significantly below normal weight. Yet they feel fat, fear being fat, diet obsessively, and sometimes exercise excessively. About half of those with anorexia display a binge-purge-depression cycle.
 - [Bulimia nervosa](#), unlike anorexia, is marked by weight fluctuations within or above normal ranges, making the condition easy to hide. Bulimia may also be triggered by a weight-loss diet, broken by gorging on forbidden foods. People with this disorder—mostly women in their late teens or early twenties (but also some men)—eat in spurts, sometimes influenced by negative emotion or by friends who are bingeing (Crandall, 1988; Haedt-Matt & Keel, 2011). In a cycle of repeating episodes, overeating is followed by compensatory vomiting, laxative use, fasting, or excessive exercise (Wonderlich et al., 2007). Preoccupied with food (craving sweet and high-fat foods), and fearful of becoming overweight, binge-purge eaters experience bouts of depression, guilt, and anxiety during and following binges (Hinz & Williamson, 1987; Johnson et al., 2002).
 - Those with [binge-eating disorder](#) engage in significant bouts of overeating, followed by remorse. But they do not purge, fast, or exercise excessively and thus may be overweight.
-

anorexia nervosa an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise.

bulimia nervosa an eating disorder in which a person's binge eating (usually of high-calorie foods) is followed by inappropriate weight-loss promoting behavior, such as vomiting, laxative use, fasting, or excessive exercise.

binge-eating disorder significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory behavior that marks bulimia nervosa.

A U.S. National Institute of Mental Health-funded study reported that, at some point during their lifetime, 0.6 percent of Americans met the criteria for anorexia, 1 percent for bulimia, and 2.8 percent for binge-eating disorder (Hudson et al., 2007). Anorexia and bulimia can be deadly. They harm the body and mind, resulting in shorter life expectancy and greater risk of suicide and nonsuicidal self-injury (Cucchi et al., 2016; Fichter & Quadflieg, 2016; Smith et al., 2016).

Understanding Eating Disorders

Eating disorders are *not* (as some have speculated) a telltale sign of childhood sexual abuse (Smolak & Murnen, 2002; Stice, 2002). The family environment may influence eating disorders in other ways, however. For example, the families of those with anorexia tend to be competitive, high-achieving, and protective (Ahrén et al., 2013; Berg et al., 2014; Yates, 1989, 1990).

Those with eating disorders often have low self-evaluations, set perfectionist standards, fret about falling short of expectations, and are intensely concerned with how others perceive them (Culbert et al., 2015; Farstad et al., 2016; Yiend et al., 2014). Some of these factors also predict teen boys' pursuit of unrealistic muscularity (Ricciardelli & McCabe, 2004).

For a look at one man's experience with eating disorders, see the **Video: Overcoming Anorexia Nervosa**.

Heredity also matters. Identical twins share these disorders more often than fraternal twins do (Culbert et al., 2009; Klump et al., 2009; Root et al., 2010). Scientists are searching for culprit genes, which may influence the body's available serotonin and estrogen (Klump & Culbert, 2007). Data from 15 studies indicate that having a gene that reduces available serotonin adds 30 percent to a person's risk of anorexia or bulimia (Calati et al., 2011).

But eating disorders also have cultural and gender components. Ideal shapes vary across culture and time. In countries with high rates of poverty—where plump means prosperous and thin can signal poverty or illness—bigger often seems better (Knickmeyer, 2001; Swami et al., 2010). Bigger less often seems better in Western cultures, where, according to 222 studies of 141,000 people, the rise in eating disorders in the last half of the twentieth century coincided with a dramatic increase in women having a poor body image (Feingold & Mazzella, 1998).

artbyjulie/Getty Images

A distorted body image underlies anorexia.

Those most vulnerable to eating disorders are also those (usually women or gay men) who most idealize thinness and have the greatest body dissatisfaction (Feldman & Meyer, 2010; Kane, 2010; Stice et al., 2010).

Should it surprise us, then, that women who view real and doctored images of unnaturally thin models and celebrities often feel ashamed, depressed, and dissatisfied with their own bodies—the very attitudes that predispose eating disorders (Grabe et al., 2008; Myers & Crowther, 2009; Tiggemann & Miller, 2010)? Eric Stice and his colleagues (2001) tested this modeling idea by giving some adolescent girls (but not others) a 15-month subscription to an American teen-fashion magazine. Compared with those who had not received the magazine, vulnerable girls—defined as those who were already dissatisfied, idealizing thinness, and lacking social support—exhibited increased body dissatisfaction and eating disorder tendencies. Even ultra-thin models do not reflect the impossible standard of the old classic Barbie doll, who had, when adjusted to a height of 5 feet 7 inches, a 32–16–29 figure (in centimeters, 81–41–74) (Norton et al., 1996).

"Up until that point, Bernice had never once had a problem with low self-esteem."

Leigh Rubes/Creators Syndicate, Inc.

There is, however, more to body dissatisfaction and anorexia than media effects (Ferguson et al., 2011). Peer influences, such as teasing, also matter. Nevertheless, the sickness of today's eating disorders stems in part from today's weight-obsessed culture—a culture that says "fat is bad" in countless ways, that motivates millions of women to diet constantly, and that invites eating binges by pressuring women to live in a constant state of

semistarvation. One former model recalled walking into a meeting with her agent, starving and with her organs failing due to anorexia (Caroll, 2013). Her agent's greeting: "Whatever you are doing, keep doing it."

"Why do women have such low self-esteem? There are many complex psychological and societal reasons, by which I mean Barbie."

Dave Barry, 1999

Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

Too thin?

Many worry that superthin models make self-starvation seem fashionable. In response to this concern, British advertising regulators banned this advertisement because the female model appeared "unhealthily thin."

Most people diagnosed with an eating disorder do improve. In one 22-year study, 2 in 3 women with anorexia nervosa or bulimia nervosa had recovered (Eddy et al., 2017). It's also possible to *prevent* people from developing these disorders. Interactive programs that teach people (especially girls over age 15) to accept their bodies reduce the likelihood of an eating disorder (Beintner et al., 2012; Melioli et al., 2016; Vocks et al., 2010). By combating cultural learning, those at risk for eating disorders can live long and healthy

lives.

* * *

The bewilderment, fear, and sorrow caused by psychological disorders are real. But, as our next topic—therapy—shows, hope, too, is real.

RETRIEVAL PRACTICE

RP-17 People with _____ (anorexia nervosa/bulimia nervosa) continue to want to lose weight even when they are underweight. Those with _____ (anorexia nervosa/bulimia nervosa) tend to have weight that fluctuates within or above normal ranges.

ANSWER: anorexia nervosa; bulimia nervosa

LOQ **15-20** [What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?](#)

LOQ **15-21** [What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?](#)

TERMS AND CONCEPTS TO REMEMBER

Test yourself on these terms by trying to compose the definition before checking your answers.

[dissociative disorders](#), p. 599

[dissociative identity disorder \(DID\)](#), p. 600

[personality disorders](#), p. 601

[antisocial personality disorder](#), p. 602

[anorexia nervosa](#), p. 605

[bulimia nervosa](#), p. 605

[binge-eating disorder](#), p. 605

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Dissociative identity disorder is controversial because

- a. dissociation is quite rare.
- b. it was reported frequently in the 1920s but rarely today.
- c. it is almost never reported outside North America.
- d. its symptoms are nearly identical to those of obsessive-compulsive disorder.

A personality disorder, such as antisocial personality, is characterized by

- a. depression.
- b. hallucinations.
- c. inflexible and enduring behavior patterns that impair social functioning.
- d. an elevated level of autonomic nervous system arousal.

PET scans of murderers' brains have revealed

- a. higher-than-normal activation in the frontal lobes.

- b. lower-than-normal activation in the frontal lobes.
- c. more frontal lobe tissue than normal.
- d. no differences in brain structures or activity.

Which of the following statements is true of bulimia nervosa?

- a. People with bulimia continue to want to lose weight even when they are underweight.
- b. Bulimia is marked by weight fluctuations within or above normal ranges.
- c. Bulimia patients often come from families that are competitive, high-achieving, and protective.
- d. If one twin is diagnosed with bulimia, the chances of the other twin's sharing the disorder are greater if they are fraternal rather than identical twins.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Kay Redfield Jamison is both an award-winning clinical psychologist and a world expert on the emotional extremes of bipolar disorder. She knows her subject firsthand: “For as long as I can remember,” she recalled in *An Unquiet Mind*, “I was frighteningly, although often wonderfully, beholden to moods. Intensely emotional as a child, mercurial as a young girl, first severely depressed as an adolescent, and then unrelentingly caught up in the cycles of manic-depressive illness [now known as bipolar disorder] by the time I began my professional life, I became, both by necessity and intellectual inclination, a student of moods” (1995, pp. 4–5). Jamison’s life was blessed with times of intense sensitivity and passionate energy. But like her father’s, it was also sometimes plagued by reckless spending, racing conversation, and sleeplessness, alternating with swings into “the blackest caves of the mind.”

Then, “in the midst of utter confusion,” she made a life-changing decision. Risking professional embarrassment, she made an appointment with a therapist, a psychiatrist she would visit weekly for years to come.

He kept me alive a thousand times over. He saw me through madness, despair, wonderful and terrible love affairs, disillusionments and triumphs, recurrences of illness, an almost fatal suicide attempt, the death of a man I greatly loved, and the enormous pleasures and aggravations of my professional life. . . . He was very tough, as well as very kind, and even though he understood more than anyone how much I felt I was losing—in energy, vivacity, and originality—by taking medication, he never [lost] sight of the overall perspective of how costly, damaging, and life threatening my illness was. . . . Although I went to him to be treated for an illness, he taught me . . . the total beholdenness of brain to mind and mind to brain (pp. 87–88).

“Psychotherapy heals,” Jamison reports. “It makes some sense of the confusion, reins in the terrifying thoughts and feelings, returns some control and hope and possibility from it all.”

This chapter explores some of the healing options available to therapists and the people who seek their help. We begin by exploring and evaluating *psychotherapies*, and then focus on *biomedical therapies* and preventing disorders.

Introduction to Therapy and the Psychological Therapies

The long history of efforts to treat psychological disorders has included a bewildering mix of harsh and gentle methods. Would-be healers have cut holes in people's heads and restrained, bled, or "beat the devil" out of them. But they also have given warm baths and massages and placed people in sunny, serene environments. They have given them drugs. And they have talked with them about childhood experiences, current feelings, and maladaptive thoughts and behaviors.

Dorothea Dix

"I . . . call your attention to the state of the Insane Persons confined within this Commonwealth, in cages."

The Granger Collection, NYC – All Rights Reserved.

The history of treatment

Visitors to eighteenth-century mental hospitals paid to gawk at patients, as though they were viewing zoo animals. William Hogarth's (1697–1764) painting captured one of these visits to London's St. Mary of Bethlehem hospital (commonly called Bedlam).

Reformers Philippe Pinel (1745–1826) and Dorothea Dix (1802–1887) pushed for gentler, more humane treatments and for constructing mental hospitals. Their efforts largely paid off. Since the 1950s, the introduction of effective drug therapies and community-based treatment programs has emptied most of those hospitals.

Treating Psychological Disorders

LOQ 16-1 LEARNING OBJECTIVE QUESTIONS How do *psychotherapy* and the *biomedical therapies* differ?

Modern Western therapies can be classified into two main categories.

- In **psychotherapy**, a trained therapist uses psychological techniques to assist someone seeking either to overcome difficulties or to achieve personal growth. The therapist may explore a client's early relationships, encourage the client to adopt new ways of thinking, or coach the client in replacing old behaviors with new ones.

- **Biomedical therapy** offers medications and other biological treatments. For example, a person with severe depression may receive antidepressants, electroconvulsive shock therapy (ECT), or deep-brain stimulation.

psychotherapy treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth.

biomedical therapy prescribed medications or procedures that act directly on the person's physiology.

The care provider's training and expertise, as well as the disorder itself, influences the choice of treatment. Psychotherapy and medication are often combined. Kay Redfield Jamison received psychotherapy in her meetings with her psychiatrist, and she took medications to control her wild mood swings.

Let's look first at some influential psychotherapy options for those treated with "talk therapies." Each is built on one or more of psychology's major theories: psychodynamic, humanistic, behavioral, and cognitive. Most of these techniques can be used one-on-one or in groups. Some therapists combine techniques. Indeed, many psychotherapists describe their approach as **eclectic**, using a blend of therapies.

eclectic approach an approach to psychotherapy that uses techniques from various forms of therapy.

Psychoanalysis and Psychodynamic Therapies

LOQ 16-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

The first major psychological therapy was Sigmund Freud's **psychoanalysis**. Although few clinicians today practice therapy as Freud did, his work

deserves discussion. It helped form the foundation for treating psychological disorders, and it continues to influence modern therapists working from the *psychodynamic* perspective.

psychoanalysis Sigmund Freud's therapeutic technique. Freud believed the patient's free associations, resistances, dreams, and transferences—and the therapist's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight.

The Goals of Psychoanalysis

Freud believed that in therapy, people could achieve healthier, less anxious living by releasing the energy they had previously devoted to id-ego-superego conflicts ([Chapter 14](#)). Freud assumed that we do not fully know ourselves. He believed that there are threatening things we *repress*—things we do not want to know, so we disavow or deny them. Psychoanalysis was Freud's method of helping people to bring these repressed feelings into conscious awareness. By helping them reclaim their unconscious thoughts and feelings, and by giving them *insight* into the origins of their disorders, the therapist (*analyst*) could help them reduce growth-impeding inner conflicts.

The Techniques of Psychoanalysis

Psychoanalytic theory emphasizes the power of childhood experiences to mold the adult. Thus, psychoanalysis is historical reconstruction. It aims to unearth the past in the hope of loosening its bonds on the present. After discarding hypnosis as an unreliable excavator, Freud turned to *free association*.

Imagine yourself as a patient using free association. You begin by relaxing, perhaps by lying on a couch. The psychoanalyst, who sits out of your line of vision, asks you to say aloud whatever comes to mind. At one moment, you're relating a childhood memory. At another, you're describing a dream or recent experience. It sounds easy, but soon you notice how often you edit your thoughts as you speak. You pause for a second before uttering an embarrassing thought. You omit what seems trivial, irrelevant, or

shameful. Sometimes your mind goes blank or you clutch up, unable to remember important details. You may joke or change the subject to something less threatening.

To the analyst, these mental blocks indicate **resistance**. They hint that anxiety lurks and you are defending against sensitive material. The analyst will note your resistance and then provide insight into its meaning. If offered at the right moment, this **interpretation**—of, say, your not wanting to talk about your mother or call, text, or message her—may illuminate the underlying wishes, feelings, and conflicts you are avoiding. The analyst may also offer an explanation of how this resistance fits with other pieces of your psychological puzzle, including those based on analysis of your dream content.

resistance in psychoanalysis, the blocking from consciousness of anxiety-laden material.

interpretation in psychoanalysis, the analyst's noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight.

Over many such sessions, your relationship patterns surface in your interaction with your therapist. You may find yourself experiencing strong positive or negative feelings for your analyst. The analyst may suggest you are **transferring** feelings, such as dependency or mingled love and anger, that you experienced in earlier relationships with family members or other important people. By exposing such feelings, you may gain insight into your current relationships.

transference in psychoanalysis, the patient's transfer to the analyst of emotions linked with other relationships (such as love or hatred for a parent).

Relatively few North American therapists now offer traditional psychoanalysis. Much of its underlying theory is not supported by scientific research ([Chapter 14](#)). Analysts' interpretations cannot be proven or

disproven. And psychoanalysis takes considerable time and money, often years of several sessions per week. Some of these problems have been addressed in the modern *psychodynamic perspective* that has evolved from psychoanalysis.

“I haven’t seen my analyst in 200 years. He was a strict Freudian. If I’d been going all this time, I’d probably almost be cured by now.”

**Woody Allen, after awakening from suspended animation in the movie
*Sleeper***

RETRIEVAL PRACTICE

RP-1 In psychoanalysis, when patients experience strong feelings for their therapist, this is called _____. Patients are said to demonstrate anxiety when they put up mental blocks around sensitive memories, indicating _____. The therapist will attempt to provide insight into the underlying anxiety by offering a(n) _____ of the mental blocks.

ANSWER: transference; resistance; interpretation

Psychodynamic Therapy

Although influenced by Freud’s ideas, [psychodynamic therapists](#) don’t talk much about id-ego-superego conflicts. Instead they try to help people understand their current symptoms by focusing on important relationships, including childhood experiences and the therapist-client relationship. “We can have loving feelings and hateful feelings toward the same person,” noted psychodynamic therapist Jonathan Shedler (2009), and “we can desire something and also fear it.” Client-therapist meetings take place once or twice a week (rather than several times weekly) and often for only a few weeks or months. Rather than lying on a couch, out of the therapist’s line of vision, clients meet with their therapist face-to-face and gain perspective by exploring defended-against thoughts and feelings.

psychodynamic therapy therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight.

"I'm more interested in hearing about the eggs you're hiding from yourself."

© The New Yorker Collection, 2009. Paul Noth, from cartoonbank.com. All Rights Reserved

Therapist David Shapiro (1999, [p. 8](#)) illustrated this with the case of a young man who had told women that he loved them, when he knew that he didn't. His explanation: They expected it, so he said it. But with his wife, who wished he would say that he loved her, he found he *couldn't* do that—"I don't know why, but I can't."

Therapist: Do you mean, then, that if you could, you would like to?

Patient: Well, I don't know. . . . Maybe I can't say it because I'm not sure
it's true. Maybe I don't love her.

Further interactions revealed that the client could not express real love because it would feel “mushy” and “soft” and therefore unmanly. He was “in conflict with himself, and . . . cut off from the nature of that conflict.” Shapiro noted that with such patients, who are estranged from themselves, therapists using psychodynamic techniques “are in a position to introduce them to themselves. We can restore their awareness of their own wishes and feelings, and their awareness, as well, of their reactions against those wishes and feelings.”

Exploring past relationship troubles may help clients understand the origin of their current difficulties. Shedler (2010a) recalled “Jeffrey’s” complaints of difficulty getting along with his colleagues and wife, who saw him as hypercritical. Jeffrey then “began responding to me as if I were an unpredictable, angry adversary.” Shedler seized this opportunity to help Jeffrey recognize the relationship pattern and its roots in the attacks and humiliation he had experienced from his alcohol-abusing father. Jeffrey was then able to work through and let go of this defensive style of responding to people. Thus, without embracing all of Freud’s theory, psychodynamic therapists aim to help people gain insight into unconscious dynamics that arise from their life experience.

Humanistic Therapies

LOQ 16-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers’ client-centered approach?

The *humanistic* perspective ([Chapter 14](#)) emphasizes people’s innate potential for self-fulfillment. Not surprisingly, humanistic therapies attempt to reduce the inner conflicts that interfere with natural development and growth. To achieve this goal, humanistic therapists try to give clients new insights. Indeed, because they share this goal, the psychodynamic and humanistic therapies are often referred to as [insight therapies](#). But humanistic therapies differ from psychodynamic therapies in many other ways:

- *Humanistic therapists aim to boost people’s self-fulfillment by helping them grow in self-awareness and self-acceptance.*
- *Promoting this growth, not curing illness, is the therapy focus.* Thus, those in therapy have become “clients” or just “persons” rather than “patients” (a change many other therapists adopted).
- *The path to growth is taking immediate responsibility for one’s feelings and actions, rather than uncovering hidden determinants.*
- *Conscious thoughts are more important than the unconscious.*
- *The present and future are more important than the past.* Therapy thus focuses on exploring feelings as they occur, rather than on achieving

insights into the childhood origins of those feelings.

insight therapies therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses.

All these themes are present in the widely used humanistic technique that Carl Rogers (1902–1987) developed and called **client-centered therapy**. In this *nondirective therapy*, the client leads the discussion. The therapist listens, without judging or interpreting, and refrains from directing the client toward certain insights. Believing that most people possess the resources for growth, Rogers (1961, 1980) encouraged therapists to foster that growth by exhibiting *acceptance*, *genuineness*, and *empathy*. When therapists enable their clients to feel unconditionally accepted, drop their facades and genuinely express their true feelings, and empathically sense and reflect their clients' feelings, the clients may deepen their self-understanding and self-acceptance (Hill & Nakayama, 2000). As Rogers (1980, [p. 10](#)) explained,

client-centered therapy a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as *active listening* within an accepting, genuine, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.)

Hearing has consequences. When I truly hear a person and the meanings that are important to him at that moment, hearing not simply his words, but him, and when I let him know that I have heard his own private personal meanings, many things happen. There is first of all a grateful look. He feels released. He wants to tell me more about his world. He surges forth in a new sense of freedom. He becomes more open to the process of change.

I have often noticed that the more deeply I hear the meanings of the person, the more there is that happens. Almost always, when a person realizes he has been deeply heard, his eyes moisten. I think in some real sense he is weeping for joy. It is as though he were saying, "Thank God, somebody heard me. Someone knows what it's like to be me."

To Rogers, "hearing" was **active listening**. The therapist echoes, restates,

and seeks clarification of what the person expresses (verbally or nonverbally) and acknowledges those expressed feelings. Active listening is now an accepted part of counseling practices in many schools, colleges, and clinics. Counselors listen attentively. They interrupt only to restate and confirm feelings, to accept what is being expressed, or to seek clarification. In the following brief excerpt, note how Rogers tried to provide a psychological mirror that would help the client see himself more clearly.

active listening empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers' client-centered therapy.

“We have two ears and one mouth that we may listen the more and talk the less.”

Zeno, 335–263 B.C.E., *Diogenes Laertius*

Rogers: Feeling that now, hm? That you're just no good to yourself, no good to anybody. Never will be any good to anybody. Just that you're completely worthless, huh?—Those really are lousy feelings. Just feel that you're no good at all, hm?

Client: Yeah. (*Muttering in low, discouraged voice*) That's what this guy I went to town with just the other day told me.

Rogers: This guy that you went to town with really told you that you were no good? Is that what you're saying? Did I get that right?

Client: M-hm.

Rogers: I guess the meaning of that if I get it right is that here's somebody that—meant something to you and what does he think of you? Why he's told you that he thinks you're no good at all. And that just really knocks the props out from under you. (*Client weeps quietly.*) It just brings the tears. (*Silence of 20 seconds*)

Client: (*Rather defiantly*) I don't care though.

Rogers: You tell yourself you don't care at all, but somehow I guess some part of you cares because some part of you weeps over it.

Michael Rougier/Getty Images

Active listening

Carl Rogers (right) empathized with a client during this group therapy session.

Can a therapist be a perfect mirror, without selecting and interpreting what is reflected? Rogers conceded that one cannot be *totally* nondirective. Nevertheless, he said, the therapist's most important contribution is to accept and understand the client. Given a nonjudgmental, grace-filled environment that provides [unconditional positive regard](#), people may accept even their worst traits and feel valued and whole.

unconditional positive regard a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help clients develop self-awareness and self-acceptance.

How can we improve communication in our own relationships by listening more actively? Three Rogers-inspired hints may help:

Paraphrase. Check your understanding by summarizing the person's words out loud, in your own words.

Invite clarification. "What might be an example of that?" may encourage the person to say more.

Reflect feelings. “It sounds frustrating” might mirror what you’re sensing from the person’s body language and intensity.

Behavior Therapies

LOQ 16-4 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

The insight therapies assume that self-awareness and psychological well-being go hand in hand. Psychodynamic therapists expect people’s problems to diminish as they gain insight into their unresolved and unconscious tensions. Humanistic therapists expect problems to diminish as people get in touch with their feelings. [Behavior therapies](#), however, doubt the healing power of self-awareness. Rather than delving deeply below the surface looking for inner causes, behavior therapists assume that problem behaviors *are* the problems. (You can become aware of why you are highly anxious during exams and still be anxious.) If phobias, sexual dysfunctions, or other maladaptive symptoms are learned behaviors, why not apply learning principles to replace them with new, constructive behaviors?

behavior therapy therapy that applies learning principles to the elimination of unwanted behaviors.

Sidney Harris/ScienceCartoonsPlus.com

Classical Conditioning Techniques

One cluster of behavior therapies derives from principles developed in Ivan Pavlov's early twentieth-century conditioning experiments ([Chapter 7](#)). As Pavlov and others showed, we learn various behaviors and emotions through classical conditioning. If we're attacked by a dog, we may thereafter have a conditioned fear response when other dogs approach. (Our fear generalizes, and all dogs become conditioned stimuli.)

Could maladaptive symptoms be examples of conditioned responses? If so, might reconditioning be a solution? Learning theorist O. H. Mowrer thought so. He developed a successful conditioning therapy for chronic bed-wetters, using a liquid-sensitive pad connected to an alarm. If the sleeping child wets the bed pad, moisture triggers the alarm, waking the child. After a number of trials, the child associates bladder relaxation with waking. In three out of four cases, the treatment has been effective and the success boosted the child's self-image (Christophersen & Edwards, 1992; Houts et al., 1994).

Can we unlearn fear responses, such as to public speaking or flying, through new conditioning? Many people have. An example: The fear of riding in an elevator is often a learned aversion to being in a confined space. [Counterconditioning](#), such as with *exposure therapy*, pairs the trigger stimulus (in this case, the enclosed space of the elevator) with a new response (relaxation) that is incompatible with fear.

counterconditioning behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*.

RETRIEVAL PRACTICE

RP-2 What might a psychodynamic therapist say about Mowrer's therapy for bed-wetting? How might a behavior therapist defend it?

ANSWER: A psychodynamic therapist might be more interested in helping the child develop insight about the underlying problems that have caused the bed-wetting response. A behavior therapist would be more likely to agree with Mowrer that the bed-wetting symptom *is* the problem, and that counterconditioning the unwanted behavior would indeed bring emotional relief.

EXPOSURE THERAPIES Picture this scene: Behavioral psychologist Mary Cover Jones is working with 3-year-old Peter, who is petrified of rabbits and other furry objects. To rid Peter of his fear, Jones plans to associate the fear-evoking rabbit with the pleasurable, relaxed response associated with eating. As Peter begins his midafternoon snack, she introduces a caged rabbit on the other side of the huge room. Peter, eagerly munching away on his crackers and drinking his milk, hardly notices. On succeeding days, she gradually moves the rabbit closer and closer. Within two months, Peter is holding the rabbit in his lap, even stroking it while he eats. Moreover, his fear of other furry objects subsides as well, having been *countered*, or replaced, by a relaxed state that cannot coexist with fear (Fisher, 1984; Jones, 1924).

Unfortunately for many who might have been helped by Jones' counterconditioning procedures, her story of Peter and the rabbit did not enter psychology's lore when it was reported in 1924. It was more than 30 years before psychiatrist Joseph Wolpe (1958; Wolpe & Plaud, 1997) refined Jones' counterconditioning technique into the [exposure therapies](#) used today. These therapies, in a variety of ways, try to change people's reactions by

repeatedly exposing them to stimuli that trigger unwanted reactions. With repeated exposure to what they normally avoid or escape, people adapt. We all experience this process in everyday life. A person moving to a new apartment may be annoyed by nearby loud traffic noise, but only for a while. The person adapts. So, too, with people who have fear reactions to specific events. Exposed repeatedly to the situation that once petrified them, with support from talk therapy, they can learn to react less anxiously (Barrera et al., 2013; Foa & McLean, 2016).

exposure therapies behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imaginary or actual situations) to the things they fear and avoid.

One exposure therapy used to treat phobias is [systematic desensitization](#). You cannot simultaneously be anxious and relaxed. Therefore, if you can repeatedly relax when facing anxiety-provoking stimuli, you can gradually eliminate your anxiety. The trick is to proceed gradually. If you feared public speaking, a behavior therapist might first help you construct a hierarchy of anxiety-triggering speaking situations. Yours might range from mildly anxiety-provoking situations (perhaps speaking up in a small group of friends) to panic-provoking situations (having to address a large audience).

systematic desensitization a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias.

Next, the therapist would train you in *progressive relaxation*. You would learn to release tension in one muscle group after another, until you achieve a comfortable, complete relaxation. Then the therapist might ask you to imagine, with your eyes closed, a mildly anxiety-arousing situation: You are having coffee with a group of friends and are trying to decide whether to speak up. If imagining the scene causes you to feel any anxiety, you will signal by raising your finger. Seeing the signal, the therapist will instruct you

to switch off the mental image and go back to deep relaxation. This imagined scene is repeatedly paired with relaxation until you feel no trace of anxiety.

The therapist will then move to the next item in your anxiety hierarchy, again using relaxation techniques to desensitize you to each imagined situation. After several sessions, you move to actual situations and practice what you had only *imagined* before, beginning with relatively easy tasks and gradually moving to more anxiety-filled ones. Conquering your anxiety in an actual situation, not just in your imagination, will increase your self-confidence (Foa & Kozak, 1986; Williams, 1987). Eventually, you may even become a confident public speaker. Often people fear not just a situation, such as public speaking, but also being incapacitated by their own fear response. As their fear subsides, so also does their fear of the fear.

“The only thing we have to fear is fear itself.”

U.S. President Franklin D. Roosevelt’s First Inaugural Address, 1933

If an anxiety-arousing situation is too expensive, difficult, or embarrassing to recreate, the therapist may recommend [virtual reality exposure therapy](#). You would don a head-mounted display unit that projects a three-dimensional virtual world. The lifelike scenes, which shift as your head turns, would be tailored to your particular fear. Experimentally treated fears include flying, heights, particular animals, and public speaking (Parsons & Rizzo, 2008). If you fear flying, you could peer out a virtual window of a simulated plane, feel the engine’s vibrations, and hear it roar as the plane taxis down the runway and takes off. In controlled studies, people participating in virtual reality exposure therapy have experienced significant relief from real-life fear (Turner & Casey, 2014).

virtual reality exposure therapy a counterconditioning technique that treats anxiety through creative electronic simulations in which people can safely face their greatest fears, such as airplane flying, spiders, or public speaking.

Jack Kearsce/Emory University; William Britten/E+/Getty Images

Virtual reality exposure therapy

Within the confines of a room, virtual reality technology exposes people to vivid simulations of feared stimuli, such as walking across a rickety bridge high off the ground.

AVERSIVE CONDITIONING An exposure therapy enables a more relaxed, positive response to an upsetting *harmless* stimulus. It helps you accept what you *should* do. **Aversive conditioning** creates a negative (aversive) response to a *harmful* stimulus (such as alcohol). It helps you to learn what you *should not* do. The aversive conditioning procedure is simple: It associates the unwanted behavior with unpleasant feelings. To treat nail biting, the therapist may suggest painting the fingernails with a nasty-tasting nail polish (Baskind, 1997). To treat alcohol use disorder, the therapist may offer the client appealing drinks laced with a drug that produces severe nausea. If that therapy links alcohol with violent nausea, the person's reaction to alcohol may change from positive to negative (**FIGURE 16.1**).

aversive conditioning associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol).

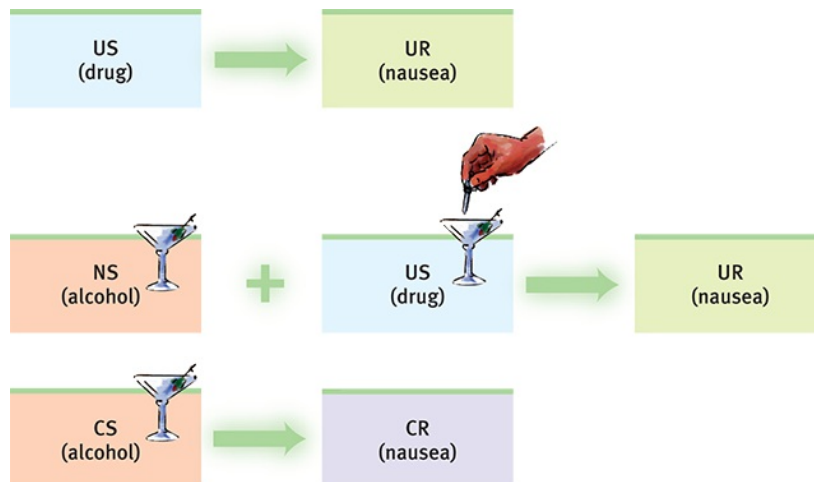

FIGURE 16.1 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 16.1 Aversion therapy for alcohol use disorder

After repeatedly imbibing an alcoholic drink mixed with a drug that produces severe nausea, some people with a history of alcohol use disorder develop at least a temporary conditioned aversion to alcohol. (Remember: US is unconditioned stimulus, UR is unconditioned response, NS is neutral stimulus, CS is conditioned stimulus, and CR is conditioned response.)

Taste aversion learning has been a successful alternative to killing predators in some animal protection programs (Dingfelder, 2010; Garcia & Gustavson, 1997). After being sickened by eating a tainted sheep, wolves may avoid sheep. Does aversive conditioning also transform humans' reactions to alcohol? In the short run it may. In one classic study, 685 hospital patients with alcohol use disorder completed an aversion therapy program (Wiens & Menustik, 1983). Over the next year, they returned for several booster treatments that paired alcohol with sickness. At the end of that year, 63 percent were not drinking alcohol. But after three years, only 33 percent were alcohol free.

In therapy, as in research, cognition influences conditioning. People know that outside the therapist's office they can drink without fear of nausea. This ability to discriminate between the therapy situation and all others can limit aversive conditioning's effectiveness. Thus, therapists often combine aversive conditioning with other treatments.

Operant Conditioning

LOQ 16-5 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

If you have learned to swim, you learned how to put your head under water without suffocating, how to pull your body through the water, and perhaps even how to dive safely. Operant conditioning shaped your swimming. You were reinforced for safe, effective behaviors. And you were naturally punished, as when you swallowed water, for improper swimming behaviors.

Consequences strongly influence our voluntary behaviors. Knowing this basic principle of operant conditioning, behavior therapists can practice *behavior modification*. They reinforce behaviors they consider desirable, and they fail to reinforce—or sometimes punish, behaviors they consider undesirable.

Using operant conditioning to solve specific behavior problems has raised hopes for some seemingly hopeless cases. Children with intellectual disabilities have been taught to care for themselves. Socially withdrawn children with autism spectrum disorder (ASD) have learned to interact. People with schizophrenia have been helped to behave more rationally in their hospital ward. In such cases, therapists used positive reinforcers to *shape* behavior. In a step-by-step manner, they rewarded closer and closer approximations of the desired behavior.

In extreme cases, treatment must be intensive. One study worked with 19 withdrawn, uncommunicative 3-year-olds with ASD. For two years, 40 hours each week, the children's parents attempted to shape their behavior (Lovaas, 1987). They positively reinforced desired behaviors and ignored or punished aggressive and self-abusive behaviors. The combination worked wonders for some children. By first grade, 9 of the 19 were functioning successfully in school and exhibiting normal intelligence. In a group of 40 comparable children not undergoing this effortful treatment, only one showed similar improvement. Later studies focused on positive reinforcement—the effective aspect of this early intensive behavioral intervention (Reichow, 2012).

Rewards used to modify behavior vary. For some people, the reinforcing power of attention or praise is sufficient. Others require concrete rewards, such as food. In institutional settings, therapists may create a [token economy](#). When people display a desired behavior, such as getting out of bed, washing,

dressings, eating, talking coherently, cleaning up their rooms, or playing cooperatively, they receive a token or plastic coin. Later, they can exchange a number of these tokens for rewards, such as candy, TV time, day trips, or better living quarters. Token economies have been used successfully in various homes, classrooms, and detention facilities, and among people with various disabilities (Matson & Boisjoli, 2009).

token economy an operant conditioning procedure in which people earn a token for exhibiting a desired behavior and can later exchange the tokens for privileges or treats.

Behavior modification critics express two concerns:

- *How durable are the behaviors?* Will people become so dependent on extrinsic rewards that the desired behaviors will stop when reinforcers stop? Behavior modification advocates believe the behaviors will endure if therapists wean people from the tokens by shifting them toward other, real-life rewards, such as social approval. Further, they point out, the desired behaviors themselves can be rewarding. As people become more socially competent, the intrinsic satisfactions of social interaction may sustain the behaviors.
- *Is it right for one human to control another's behavior?* Those who set up token economies deprive people of something they desire and decide which behaviors to reinforce. To critics, this whole process feels too authoritarian. Advocates reply that control already exists: People's destructive behavior patterns are being maintained and perpetuated by natural reinforcers and punishers in their environments. Isn't using positive rewards to reinforce adaptive behavior more humane than institutionalizing or punishing people? Advocates also argue that the right to effective treatment and an improved life justifies temporary deprivation.

RETRIEVAL PRACTICE

RP-3 What are the *insight therapies*, and how do they differ from *behavior therapies*?

ANSWER: The *insight therapies*—psychodynamic and humanistic therapies—seek to relieve problems by providing an understanding of their origins. *Behavior therapies* assume the problem behavior *is* the problem and treat it directly, paying less attention to its origins.

RP-4 Some maladaptive behaviors are learned. What hope does this fact provide?

ANSWER: If a behavior can be learned, it can be *unlearned*, and replaced by other more adaptive responses.

RP-5 Exposure therapies and aversive conditioning are applications of _____ conditioning. Token economies are an application of _____ conditioning.

ANSWER: classical; operant

Cognitive Therapies

LOQ 16-6 What are the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy?

People with specific fears and problem behaviors may respond to behavior therapy. But how might behavior therapists modify the wide assortment of behaviors that accompany depressive disorders? Or treat people with generalized anxiety disorder, where unfocused anxiety doesn't lend itself to a neat list of anxiety-triggering situations? The *cognitive revolution* that has profoundly changed other areas of psychology during the last half-century has influenced therapy as well.

The [cognitive therapies](#) assume that our thinking colors our feelings ([FIGURE 16.2](#)). Between an event and our response lies the mind. Self-blaming and overgeneralized explanations of bad events feed depression. Anxiety arises from an “attention bias to threat” (MacLeod & Clarke, 2015). If depressed, we may interpret a suggestion as criticism, disagreement as dislike, praise as flattery, friendliness as pity. Dwelling on such thoughts

sustains negative thinking. Cognitive therapies aim to help people change their mind with new, more constructive ways of perceiving and interpreting events (Kazdin, 2015).

cognitive therapy therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions.

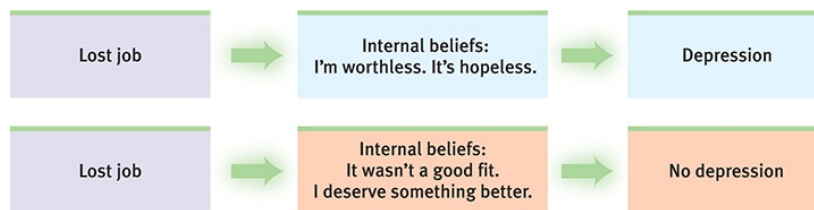

FIGURE 16.2 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 16.2 A cognitive perspective on psychological disorders

The person's emotional reactions are produced not directly by the event, but by the person's thoughts in response to the event.

“Life does not consist mainly, or even largely, of facts and happenings. It consists mainly of the storm of thoughts that are forever blowing through one's mind.”

Mark Twain, 1835–1910

Beck's Therapy for Depression

In the late 1960s, a woman left a party early. Things had not gone well. She felt disconnected from the other party-goers and assumed no one cared for her. A few days later, she visited therapist Aaron Beck. Rather than go down the traditional path to her childhood, Beck challenged her thinking. After she then listed a dozen people who *did* care for her, Beck realized that challenging people's automatic negative thoughts could be therapeutic. And thus was born his cognitive therapy, which assumes that changing people's thinking can change their functioning (Spiegel, 2015).

Depressed people, Beck found, often reported dreams with negative themes of loss, rejection, and abandonment. These thoughts extended into

their waking thoughts, and even into therapy, as clients recalled and rehearsed their failings and worst impulses (Kelly, 2000). With cognitive therapy, Beck and his colleagues (1979) sought to reverse clients' negativity about themselves, their situations, and their futures. With this technique, gentle questioning seeks to reveal irrational thinking, and then to persuade people to remove the dark glasses through which they view life (Beck et al., 1979, pp. 145–146):

Client: I agree with the descriptions of me but I guess I don't agree that the way I think makes me depressed.

Beck: How do you understand it?

Client: I get depressed when things go wrong. Like when I fail a test.

Beck: How can failing a test make you depressed?

Client: Well, if I fail I'll never get into law school.

Beck: So failing the test means a lot to you. But if failing a test could drive people into clinical depression, wouldn't you expect everyone who failed the test to have a depression? . . . Did everyone who failed get depressed enough to require treatment?

Client: No, but it depends on how important the test was to the person.

Beck: Right, and who decides the importance?

Client: I do.

Beck: And so, what we have to examine is your way of viewing the test (or the way that you think about the test) and how it affects your chance of getting into law school. Do you agree?

Client: Right.

Beck: Do you agree that the way you interpret the results of the test will affect you? You might feel depressed, you might have trouble sleeping, not feel like eating, and you might even wonder if you should drop out of the course.

Client: I have been thinking that I wasn't going to make it. Yes, I agree.

Beck: Now what did failing mean?

Client: (tearful) That I couldn't get into law school.

Beck: And what does that mean to you?

Client: That I'm just not smart enough.

Beck: Anything else?

Client: That I can never be happy.

Beck: And how do these thoughts make you feel?

Client: Very unhappy.

Beck: So it is the meaning of failing a test that makes you very unhappy. In fact, believing that you can never be happy is a powerful factor in producing unhappiness. So, you get yourself into a trap—by definition, failure to get into law school equals “I can never be happy.”

We often think in words. Therefore, getting people to change what they say to themselves is an effective way to change their thinking. Perhaps you can identify with the anxious students who, before an exam, make matters worse with self-defeating thoughts: “This exam’s probably going to be impossible. Everyone seems so relaxed and confident. I wish I were better prepared. I’m so nervous I’ll forget everything.” Psychologists call this sort of relentless, overgeneralized, self-blaming behavior *catastrophizing*.

To change such negative self-talk, therapists have offered *stress inoculation training*: teaching people to restructure their thinking in stressful situations (Meichenbaum, 1977, 1985). Sometimes it may be enough simply to say more positive things to oneself: “Relax. The exam may be hard, but it will be hard for everyone else, too. I studied harder than most people. Besides, I don’t need a perfect score to get a good grade.” After learning to “talk back” to negative thoughts, depression-prone children, teens, and college students have shown a greatly reduced rate of future depression (Reivich et al., 2013; Seligman et al., 2009). To a large extent, it is the thought that counts. For a sampling of commonly used cognitive therapy techniques, see [TABLE 16.1](#).)

TABLE 16.1

Selected Cognitive Therapy Techniques

Aim of Technique	Technique	Therapists’ Directives

<i>Reveal beliefs</i>	Question your interpretations	Explore your beliefs, revealing faulty assumptions such as “I must be liked by everyone.”
	Rank thoughts and emotions	Gain perspective by ranking your thoughts and emotions from mildly to extremely upsetting.
<i>Test beliefs</i>	Examine consequences	Explore difficult situations, assessing possible consequences and challenging faulty reasoning.
	Decatastrophize thinking	Work through the actual worst-case consequences of the situation you face (it is often not as bad as imagined). Then determine how to cope with the real situation you face.
<i>Change beliefs</i>	Take appropriate responsibility	Challenge total self-blame and negative thinking, noting aspects for which you may be truly responsible, as well as aspects that aren’t your responsibility.
	Resist extremes	Develop new ways of thinking and feeling to replace maladaptive habits. For example, change from thinking “I am a total failure” to “I got a failing grade on that paper, and I can make these changes to succeed next time.”

It’s not just depressed people who can benefit from positive self-talk. We all talk to ourselves (thinking “I wish I hadn’t said that” can protect us from repeating the blunder). The findings of nearly three dozen sport psychology studies show that self-talk interventions can enhance the learning of athletic skills (Hatzigeorgiadis et al., 2011). For example, novice basketball players may be trained to think “focus” and “follow through,” swimmers to think “high elbow,” and tennis players to think “look at the ball.” People anxious

about public speaking have grown in confidence if asked to recall a speaking success, and then to “Explain WHY you were able to achieve such a successful performance” (Zunick et al., 2015).

Cognitive-Behavioral Therapy

“The trouble with most therapy,” said therapist Albert Ellis (1913–2007), “is that it helps you to feel better. But you don’t get better. You have to back it up with action, action, action.” [Cognitive-behavioral therapy \(CBT\)](#) takes a combined approach to depression and other disorders. This widely practiced *integrative* therapy aims to alter not only the way people *think* but also the way they *act*. Like other cognitive therapies, CBT seeks to make people aware of their irrational negative thinking and to replace it with new ways of thinking. And like other behavior therapies, it trains people to *practice* the more positive approach in everyday settings.

cognitive-behavioral therapy (CBT) a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior).

Anxiety, depressive disorders, and bipolar disorder share a common problem: emotion regulation (Aldao & Nolen-Hoeksema, 2010; Szkodny et al., 2014). An effective CBT program for these emotional disorders trains people both to replace their catastrophizing thinking with more realistic appraisals, and, as homework, to practice behaviors that are incompatible with their problem (Kazantzis et al., 2010a,b; Moses & Barlow, 2006). A person might keep a log of daily situations associated with negative and positive emotions, and engage more in activities that lead to feeling good. Those who fear social situations might learn to restrain the negative thoughts surrounding their social anxiety and practice approaching people.

CBT effectively treats people with obsessive-compulsive disorder (Öst et al., 2015). In one classic study, people learned to prevent their compulsive behaviors by relabeling their obsessive thoughts (Schwartz et al., 1996). Feeling the urge to wash their hands again, they would tell themselves, “I’m having a compulsive urge.” They would explain to themselves that the hand-washing urge was a result of their brain’s abnormal activity, which they had previously viewed in PET scans. Then, instead of giving in, they would spend 15 minutes in an enjoyable, alternative behavior—practicing an instrument, taking a walk, gardening. This helped “unstuck” the brain by shifting attention and engaging other brain areas. For two or three months, the weekly therapy sessions continued, with relabeling and refocusing practice at home. By the study’s end, most participants’ symptoms had diminished and their PET scans revealed normalized brain activity. Many other studies confirm CBT’s effectiveness for treating anxiety, depression, and eating disorders (Cristea et al., 2015; Milrod et al., 2015; Turner et al., 2016). Even online CBT quizzes and exercises—therapy without a face-to-face therapist—have helped alleviate insomnia, depression, and anxiety (Andersson, 2016; Christensen et al., 2016; Kampmann et al., 2016; Vigerland et al., 2016).

Lara Jo Regan

Cognitive therapy for eating disorders aided by journaling

Cognitive therapists guide people toward new ways of explaining their good and bad experiences. By recording positive events and how she has enabled them, this woman may become more mindful of her self-control and more optimistic.

A newer CBT variation, *dialectical behavior therapy (DBT)*, helps change

harmful and even suicidal behavior patterns (Linehan et al., 2015; Mehlum et al., 2016; Valentine et al., 2015). *Dialectical* means “opposing,” and this therapy attempts to make peace between two opposing forces—acceptance and change. Therapists create an accepting and encouraging environment, helping clients feel they have an ally who will offer them constructive feedback and guidance. In individual sessions, clients learn new ways of thinking that help them tolerate distress and regulate their emotions. They also receive training in social skills and in mindfulness meditation, which helps alleviate depression (Gu et al., 2015; Kuyken et al., 2016). Group training sessions offer additional opportunities to practice new skills in a social context, with further practice as homework.

RETRIEVAL PRACTICE

RP-6 How do the humanistic and cognitive therapies differ?

ANSWER: By reflecting clients’ feelings in a nondirective setting, the *humanistic therapies* attempt to foster personal growth by helping clients become more self-aware and self-accepting. By making clients aware of self-defeating patterns of thinking, *cognitive therapies* guide people toward more adaptive ways of thinking about themselves and their world.

RP-7 A critical attribute of the _____ developed by Aaron Beck focuses on the belief that changing people’s thinking can change their functioning.

ANSWER: cognitive therapy.

RP-8 What is cognitive-behavioral therapy, and what sorts of problems does this therapy best address?

ANSWER: This integrative therapy helps people change self-defeating thinking and behavior. It has been shown to be effective for those with anxiety disorders, obsessive-compulsive disorder, depressive disorders, bipolar disorder, and eating disorders.

Group and Family Therapies

LOQ 16-7 What are the aims and benefits of group and family therapies?

Group Therapy

Except for traditional psychoanalysis, most therapies may also occur in small groups. [Group therapy](#) does not provide the same degree of therapist involvement with each client. However, it offers other benefits:

- *It saves therapists' time and clients' money*, and often is no less effective than individual therapy (Burlingame et al., 2016).
- *It offers a social laboratory for exploring social behaviors and developing social skills*. Therapists frequently suggest group therapy for people experiencing frequent conflicts or whose behavior distresses others. The therapist guides people's interactions as they discuss issues and try out new behaviors.
- *It enables people to see that others share their problems*. It can be a relief to discover that others, despite their composure, experience some of the same troublesome feelings and behaviors (Ooi et al., 2016).
- *It provides feedback as clients try out new ways of behaving*. Hearing that you look poised, even though you feel anxious and self-conscious, can be very reassuring.

John Moore/Getty Images

Family therapy

This type of therapy often acts as a preventive mental health strategy and may include marriage therapy, as shown here at a retreat for U.S. military families. The therapist helps family members understand how their ways of relating to one another create problems. The treatment's emphasis is not on changing the individuals, but on changing their relationships and interactions.

group therapy therapy conducted with groups rather than individuals, providing benefits from group interaction.

Family Therapy

One special type of group interaction, [family therapy](#), assumes that no person is an island: We live and grow in relation to others, especially our families. We struggle to differentiate ourselves from our families, but we also need to connect with them emotionally. These two opposing tendencies can create stress for both the individual and the family.

family therapy therapy that treats people in the context of their family system. Views an individual's unwanted behaviors as influenced by, or directed at, other family members.

Family therapists tend to view families as systems, in which each person's actions trigger reactions from others. A child's rebellion, for example, affects and is affected by other family tensions. Therapists are often successful in helping family members identify their roles within the family's social system, improve communication, and discover new ways of preventing or resolving conflicts (Hazelrigg et al., 1987; Shadish et al., 1993).

Self-Help Groups

More than 100 million Americans have belonged to small religious, interest, or support groups that meet regularly—with 9 in 10 reporting that group members “support each other emotionally” (Gallup, 1994). One analysis of online support and self-help groups reported that most focus on stigmatized or hard-to-discuss illnesses (Davison et al., 2000). AIDS patients were 250 times more likely than hypertension patients to be in support groups. People with anorexia and alcohol use disorder often join groups; those with migraines and ulcers usually do not.

The grandparent of support groups, Alcoholics Anonymous (AA), reports having 2.1 million members in 118,000 groups worldwide. Its famous 12-step program, emulated by many other self-help groups, asks members to admit their powerlessness, to seek help from a higher power and from one another, and (the twelfth step) to take the message to others in need of it (Galanter, 2016). Studies of 12-step programs such as AA have found that they help reduce alcohol use disorder at rates comparable to other treatment interventions (Ferri et al., 2006; Moos & Moos, 2005). In an eight-year, \$27 million investigation, AA participants reduced their drinking sharply, as did those assigned to CBT or an alternative therapy (Project Match, 1997). Another study of 2300 veterans who sought treatment for alcohol use disorder found that a high level of AA involvement was followed by diminished alcohol problems (McKellar et al., 2003). The more meetings AA members attend, the greater their alcohol abstinence (Moos & Moos, 2006). Those whose personal stories include a “redemptive narrative”—who see something good as having come from their experience—more often sustain sobriety (Dunlop & Tracy, 2013).

With more than 2 million members worldwide, AA is said to be “the largest organization on Earth that nobody wanted to join” (Finlay, 2000).

In an individualist age, with more and more people living alone or feeling isolated, the popularity of support groups—for the addicted, the bereaved, the divorced, or simply those seeking fellowship and growth—may reflect a longing for community and connectedness.

* * *

For a synopsis of these modern psychotherapies, see [TABLE 16.2](#).

TABLE 16.2
Comparing Modern Psychotherapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Psychodynamic</i>	Unconscious conflicts from childhood experiences	Reduce anxiety through self-insight.	Interpret patients' memories and feelings.
<i>Client-centered</i>	Barriers to self-understanding and self-acceptance	Enable growth via unconditional positive regard, acceptance, genuineness, and empathy.	Listen actively and reflect clients' feelings.
<i>Behavior</i>	Dysfunctional behaviors	Learn adaptive behaviors; extinguish problem ones.	Use classical conditioning (via exposure or aversion therapy) or

			operant conditioning (as in token economies).
<i>Cognitive</i>	Negative, self-defeating thinking	Promote healthier thinking and self-talk.	Train people to dispute negative thoughts and attributions.
<i>Cognitive-behavioral</i>	Self-harmful thoughts and behaviors	Promote healthier thinking and adaptive behaviors.	Train people to counter self-harmful thoughts and to act out their new ways of thinking.
<i>Group and family</i>	Stressful relationships	Heal relationships.	Develop an understanding of family and other social systems, explore roles, and improve communication.

REVIEW Introduction to Therapy and the Psychological Therapies

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

A therapist who helps patients search for the unconscious roots of their problem and offers interpretations of their behaviors, feelings, and dreams, is drawing from

- a. psychoanalysis.
- b. humanistic therapies.
- c. client-centered therapy.
- d. behavior therapy.

_____therapies are designed to help individuals discover the thoughts and feelings that guide their motivation and behavior.

Compared with psychoanalysts, humanistic therapists are more likely to emphasize

- a. hidden or repressed feelings.
- b. childhood experiences.
- c. psychological disorders.

d. self-fulfillment and growth.

A therapist who restates and clarifies the client's statements is practicing the technique of _____.

The goal of behavior therapy is to

- a. identify and treat the underlying causes of the problem.
- b. improve learning and insight.
- c. eliminate the unwanted behavior.
- d. improve communication and social sensitivity.

Behavior therapies often use _____ techniques such as systematic desensitization and aversive conditioning to encourage clients to produce new responses to old stimuli.

The technique of _____ teaches people to relax in the presence of progressively more anxiety-provoking stimuli.

After a near-fatal car accident, Rico developed such an intense fear of driving on the freeway that he takes lengthy alternative routes to work each day. Which psychological therapy might best help Rico overcome his phobia, and why?

At a treatment center, people who display a desired behavior receive coins that they can later exchange for other rewards. This is an example of a(n) _____.

Cognitive therapy has been especially effective in treating

- a. nail biting.
- b. phobias.
- c. alcohol use disorder.
- d. depression.

_____ - _____ therapy helps people to change their self-defeating ways of thinking and to act out those changes in their daily behavior.

In family therapy, the therapist assumes that

- a. only one family member needs to change.
- b. each person's actions trigger reactions from other family members.
- c. dysfunctional family behaviors are based largely on genetic factors.
- d. therapy is most effective when clients are treated apart from the family unit.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Evaluating Psychotherapies

Many people presume psychotherapy's effectiveness. "Seek counseling" or "Ask your mate to find a therapist," advice columnists often urge. Before 1950, psychiatrists were the primary providers of mental health care. Today's providers include clinical and counseling psychologists; clinical social workers; pastoral, marital, abuse, and school counselors; and psychiatric nurses. With such an enormous outlay of time as well as money and effort, it is important to ask: Are the millions of people worldwide justified in placing their hopes in psychotherapy?

Is Psychotherapy Effective?

LOQ 16-8 Does psychotherapy work? How can we know?

The question, though simply put, is not simply answered. If an infection quickly clears, we may assume an antibiotic has been effective. But how can we assess psychotherapy's effectiveness? By how we feel about our progress? By how our therapist feels about it? By how our friends and family feel about it? By how our behavior has changed?

Jon Carter/Cartoonstock

Clients' Perceptions

If clients' testimonials were the only measuring stick, we could strongly affirm psychotherapy's effectiveness. Consider the 2900 *Consumer Reports* readers who related their experiences with mental health professionals (1995; Kotkin et al., 1996; Seligman, 1995). How many were at least "fairly well satisfied"? Almost 90 percent (as was Kay Redfield Jamison, as we saw at this chapter's beginning). Among those who recalled feeling *fair* or *very poor* when beginning therapy, 9 in 10 now were feeling *very good*, *good*, or at least so-so. We have their word for it—and who should know better?

We should not dismiss these testimonials. But critics note reasons for skepticism:

- ***People often enter therapy in crisis.*** When, with the normal ebb and flow of events, the crisis passes, people may attribute their improvement to the therapy. Depressed people often get better no matter what they do.
- ***Clients believe that treatment will be effective.*** The *placebo effect* is the healing power of positive expectations.
- ***Clients generally speak kindly of their therapists.*** Even if the problems remain, clients "work hard to find something positive to say. The therapist had been very understanding, the client had gained a new perspective, he

learned to communicate better, his mind was eased, anything at all so as not to have to say treatment was a failure” (Zilbergeld, 1983, [p. 117](#)).

- ***Clients want to believe the therapy was worth the effort.*** To admit investing time and money in something ineffective is like admitting to having one’s car serviced repeatedly by a mechanic who never fixes it.

As earlier chapters document, we are prone to selective and biased recall and to making judgments that confirm our beliefs. Psychologists call this *effort justification*. Consider the testimonials gathered in a massive experiment with over 500 Massachusetts boys, aged 5 to 13 years, many of whom seemed bound for delinquency. By the toss of a coin, half the boys were assigned to a 5-year treatment program. The treated boys were visited by counselors twice a month. They participated in community programs, and they received academic tutoring, medical attention, and family assistance as needed. Some 30 years later, Joan McCord (1978, 1979) located 485 participants, sent them questionnaires, and checked public records from courts, mental hospitals, and other sources. Was the treatment successful?

Client testimonials were glowing. Some men noted that, had it not been for their counselors, “I would probably be in jail,” “My life would have gone the other way,” or “I think I would have ended up in a life of crime.” Court records offered apparent support: Even among the “difficult” boys in the treatment group, 66 percent had no official juvenile crime record.

But recall psychology’s most powerful tool for sorting reality from wishful thinking: the *control group*. For every boy in the treatment group, there was a similar boy in a control group, receiving no counseling. Of these untreated men, 70 percent had no juvenile record. On several other measures, such as a record of having committed a second crime, alcohol use disorder, death rate, and job satisfaction, the untreated men exhibited slightly *fewer* problems. The glowing testimonials of those treated had been unintentionally deceiving.

Clinicians’ Perceptions

If clinicians’ perceptions were proof of therapy’s effectiveness, we would have even more reason to celebrate. Case studies of successful treatment abound. The problem is that clients justify entering psychotherapy by

emphasizing their unhappiness and justify leaving by emphasizing their well-being. Therapists treasure compliments from clients as they say good-bye or later express their gratitude, but they hear little from clients who experience only temporary relief and seek out new therapists for their recurring problems. Thus, therapists are most aware of the failures of other therapists—those whose clients, having experienced only temporary relief, are now seeking a new therapist for their recurring problems. The same person, with the same recurring anxieties, depression, or marital difficulty, may be a “success” story in several therapists’ files. Moreover, therapists, like the rest of us, are vulnerable to cognitive errors, such as *confirmation bias* and *illusory correlation* (Lilienfeld et al., 2015).

Outcome Research

How, then, can we objectively measure the effectiveness of psychotherapy? What *outcomes* can we expect—what types of people and problems are helped, and by what type of psychotherapy?

In search of answers, psychologists have turned to the well-traveled path of controlled research. Similar research in the 1800s transformed the field of medicine when skeptical physicians began to realize that many patients were dying despite receiving fashionable treatments (bleeding, purging), and others were getting better on their own. Sorting fact from superstition required observing patients and recording outcomes with and without a particular treatment. Typhoid fever patients, for example, often improved after being bled, convincing most physicians that the treatment worked. Then came the shock. A control group was given mere bed rest, and after five weeks of fever, 70 percent improved, showing that the bleeding was worthless (Thomas, 1992).

In the twentieth century, psychology, with its many different therapy options, faced a similar challenge. British psychologist Hans Eysenck (1952) launched a spirited debate when he summarized 24 studies of psychotherapy outcomes. He found that two-thirds of those receiving psychotherapy for disorders not involving hallucinations or delusions improved markedly. To this day, no one disputes that optimistic estimate.

Why, then, are we still debating psychotherapy’s effectiveness? Because Eysenck also reported similar improvement among *untreated* persons, such

as those who were on waiting lists for treatment. With or without psychotherapy, he said, roughly two-thirds improved noticeably. Time was a great healer.

Later research revealed shortcomings in Eysenck's analyses. His sample was small—only 24 outcome studies in 1952, compared with the hundreds available today. The best of these are *randomized clinical trials*, in which researchers randomly assign people on a waiting list to therapy or to no therapy. Later, they evaluate everyone and compare outcomes, with tests and assessments by others who don't know whether therapy was given.

A glimpse of psychotherapy's overall effectiveness can then be provided by means of a [meta-analysis](#), a statistical procedure that combines the conclusions of a large number of different studies. Simply said, meta-analyses give us the bottom-line result of lots of studies. Therapists welcomed the first meta-analysis of some 475 psychotherapy outcome studies (Smith et al., 1980). It showed that the average therapy client ends up better off than 80 percent of the untreated individuals on waiting lists ([FIGURE 16.3](#)). The claim is modest—by definition, about 50 percent of untreated people also are better off than the average untreated person. Nevertheless, Mary Lee Smith and her colleagues exulted that “psychotherapy benefits people of all ages as reliably as schooling educates them, medicine cures them, or business turns a profit” ([p. 183](#)).

meta-analysis a procedure for statistically combining the results of many different research studies.

FIGURE 16.3 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Data from Smith et al., 1980

FIGURE 16.3 Treatment versus no treatment

These two normal distribution curves based on data from 475 studies show the improvement of untreated people and psychotherapy clients. The outcome for the average therapy client surpassed the outcome for 80 percent of the untreated people. (Data from Smith et al., 1980.)

Dozens of subsequent summaries have now examined psychotherapy's effectiveness. Their verdict echoes earlier results: *Those not undergoing therapy often improve, but those undergoing therapy are more likely to improve—and to improve more quickly and with less risk of relapse* (Kolovos et al., 2017; Weisz et al., 2017). (One qualification: Compared with studies that find no therapy benefit, those that do find a positive therapy effect are more likely to get published [Driessen et al., 2015].) Even so, many people exhibit a more stable and outgoing personality after therapy (Roberts et al., 2017). And some people experience sudden symptom reductions between their treatment sessions for depression or anxiety. Those “sudden gains” bode well for long-term improvement (Aderka et al., 2012).

Feng Li/Getty Images

Trauma

These women were mourning the tragic loss of lives and homes in the 2010 earthquake in China. Those who suffer through such trauma may benefit from counseling, though many people recover on their own or with the help of supportive relationships with family and friends. “Life itself still remains a very effective therapist,” noted psychodynamic therapist Karen Horney (*Our Inner Conflicts*, 1945).

Psychotherapy also can be cost-effective. Studies show that when people seek psychological treatment, their search for other medical treatment drops—by 16 percent in one digest of 91 studies (Chiles et al., 1999). Given the staggering annual cost of psychological disorders and substance abuse—including crime, accidents, lost work, and treatment—psychotherapy is a good investment, much like money spent on prenatal and well-baby care (Chisholm et al., 2016; Ising et al., 2015). Both *reduce* long-term costs. Boosting employees’ psychological well-being can lower medical costs, improve work efficiency, and diminish absenteeism.

But note that the claim—that psychotherapy, *on average*, is somewhat effective—refers to no one therapy in particular. It is like reassuring lung-cancer patients that “on average,” medical treatment of health problems is effective. But what distressed people—and those paying for their therapy—want to know is whether a *particular* treatment is effective for their specific problems.

RETRIEVAL PRACTICE

RP-9 How might the *placebo effect* bias clients' and clinicians' appraisals of the effectiveness of psychotherapies?

ANSWER: The *placebo effect* is the healing power of *belief* in a treatment. Patients and therapists who expect a treatment to be effective may believe it was.

Which Psychotherapies Work Best?

LOQ 16-9 Are some psychotherapies more effective than others for specific disorders?

The early statistical summaries and surveys did not find that any one type of psychotherapy is generally superior (Smith & Glass, 1977, Smith et al., 1980). Later studies have similarly found little connection between clients' outcomes and their clinicians' experience, training, supervision, and licensing (Barth et al., 2013; Cuijpers, 2017; Kivlighan et al., 2015). A *Consumer Reports* survey confirmed this result. Were clients treated by a psychiatrist, psychologist, or social worker? Were they seen in a group or individual context? Did the therapist have extensive or relatively limited training and experience? It didn't matter. Clients seemed equally satisfied (Seligman, 1995).

So, was the dodo bird in *Alice in Wonderland* right: "Everyone has won and all must have prizes"? Not quite. One general finding emerges from the studies: The more specific the problem, the greater the hope that psychotherapy might solve it (Singer, 1981; Westen & Morrison, 2001). Those who experience phobias or panic, who are unassertive, or who are frustrated by sexual performance problems can hope for improvement. Those with less-focused problems, such as depression and anxiety, usually benefit in the short term but often relapse later. There often is also an overlapping or *comorbidity* of disorders.

"Different sores have different salves."

Nevertheless, some forms of therapy do get prizes for effectively treating *particular* problems:

- *Cognitive and cognitive-behavioral therapies*—anxiety, posttraumatic stress disorder, insomnia, and depression (Qaseem et al., 2016; Scaini et al., 2016; Tolin, 2010).
- *Behavioral conditioning therapies*—specific behavior problems, such as bed-wetting, phobias, compulsions, marital problems, and sexual dysfunctions (Baker et al., 2008; Hunsley & DiGiulio, 2002; Shadish & Baldwin, 2005).
- *Psychodynamic therapy*—depression and anxiety (Driessen et al., 2010; Leichsenring & Rabung, 2008; Shedler, 2010b).
- *Nondirective (client-centered) counseling*—mild to moderate depression (Cuijpers et al., 2012).

The evaluation question—which therapies get prizes and which do not?—lies at the heart of what some call psychology’s civil war. To what extent should science guide both clinical practice and the willingness of health care providers and insurers to pay for psychotherapy? On one side are research psychologists using scientific methods to extend the list of well-defined and validated therapies for various disorders. They decry clinicians who “give more weight to their personal experience than to science” (Baker et al., 2008). On the other side are nonscientist therapists who view their practice as more art than science: People are too complex and psychotherapy is too intuitive to describe in a manual or test in an experiment. Between these two factions stand the science-oriented clinicians calling for [evidence-based practice](#), which has been endorsed by the American Psychological Association and others (2006; Lilienfeld et al., 2013). Therapists using this approach integrate the best available research with clinical expertise and with patient preferences and characteristics ([FIGURE 16.4](#)). After rigorous evaluation, clinicians apply therapies suited to their own skills and their patients’ unique situations. Increasingly, insurer and government support for mental health services requires evidence-based practice.

evidence-based practice clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences.

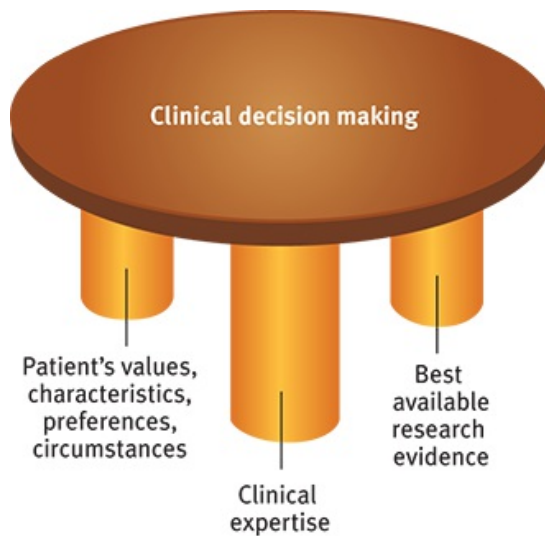

FIGURE 16.4 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

FIGURE 16.4 Evidence-based clinical decision making

The ideal clinical decision making can be visualized as a three-legged stool, upheld by research evidence, clinical expertise, and knowledge of the patient.

RP-10 Therapy is most likely to be helpful for those with problems that _____ (are/are not) well-defined.

ANSWER: are

Evaluating Alternative Therapies

LOQ 16-10 How do alternative therapies fare under scientific scrutiny?

The tendency of many abnormal states of mind to return to normal, combined

with the placebo effect (the healing power of mere belief in a treatment), creates fertile soil for pseudotherapies. Bolstered by anecdotes, boosted by the media, and broadcast on the Internet, alternative therapies—newer, nontraditional therapies, which often claim healing powers for various ailments—can spread like wildfire. In one national survey, 57 percent of those with a history of anxiety attacks and 54 percent of those with a history of depression had used alternative treatments, such as herbal medicine, massage, and spiritual healing (Kessler et al., 2001).

Proponents of alternative therapies often feel that their personal testimonials are evidence enough. But how well do these therapies stand up to scientific scrutiny? There is little evidence for or against most of them. Some, however, have been the subject of controlled research. No prizes—and no scientific support—go to certain alternative therapies (Arkowitz & Lilienfeld, 2006; Lilienfeld et al., 2015). We would all be wise to avoid *energy therapies* that propose to manipulate the client's invisible "energy fields"; hand-guided *facilitated communication* with uncommunicative people; *recovered-memory therapies* that aim to unearth "repressed memories" of early child abuse; and *rebirthing therapies* that reenact the supposed trauma of a client's birth.

As with medical treatments, some psychological treatments are not only ineffective but also harmful (Barlow, 2010; Castonguay et al., 2010; Dimidjian & Hollon, 2010). The National Science and Technology Council has cited the Scared Straight program (seeking to deter children and youth from crime by having them visit with adult inmates) as an example of one such well-intentioned but ineffective program. The American Psychiatric Association and British Psychological Society have warned against "conversion therapy" for those with same-sex attractions. Conversion therapies, including "reparative therapy," aim to "repair" "something that is not a mental illness and therefore does not require therapy," declared American Psychological Association president Barry Anton (2015). "There is insufficient scientific evidence that they work, and they have the potential to harm the client."

Let's look more closely at two other alternative therapies. As we do, remember that sifting sense from nonsense requires the scientific attitude: being skeptical but not cynical, open to surprises but not gullible.

Eye Movement Desensitization and Reprocessing (EMDR)

EMDR (eye movement desensitization and reprocessing) is a therapy adored by thousands and dismissed by thousands more as a sham. Psychologist Francine Shapiro (1989, 2007, 2012) developed EMDR while walking in a park and observing that anxious thoughts vanished as her eyes spontaneously darted about. Back in the clinic, she had people imagine traumatic scenes while she triggered eye movements by waving her finger in front of their eyes, supposedly enabling them to unlock and reprocess previously frozen memories. Thousands of mental health professionals from more than 75 countries have since undergone training (EMDR, 2011).

Does EMDR work? Shapiro (1999, 2002) believes it does, and she cites four studies in which it worked for 84 to 100 percent of single-trauma victims. Other studies have confirmed its benefits with trauma survivors (Chen et al., 2015). But why, wonder skeptics, would rapidly moving one's eyes while recalling traumas be therapeutic? Some argue that eye movements relax or distract patients, thus allowing memory-associated emotions to extinguish (Gunter & Bodner, 2008). (Part of therapeutic change is calling up old memories and associating them with new emotions [Lane et al., 2015].) Others believe the eye movements themselves are *not* the therapeutic ingredient (nor is watching high-speed Ping-Pong therapeutic). Trials in which people imagined traumatic scenes and tapped a finger, or just stared straight ahead while the therapist's finger wagged, have also produced therapeutic results (Deville, 2003).

Skeptics acknowledge that EMDR does work better than doing nothing (Lilienfeld & Arkowitz, 2007). But they suspect that what is therapeutic is the combination of exposure therapy—repeatedly calling up traumatic memories and reconsolidating them in a safe and reassuring context—and perhaps some placebo effect.

“Studies indicate that EMDR is just as effective with fixed eyes. If that conclusion is right, what's useful in the therapy (chiefly behavioral desensitization) is not new, and what's new is superfluous.”

Harvard Mental Health Letter, 2002

Light Exposure Therapy

Have you ever found yourself oversleeping, gaining weight, and feeling lethargic, perhaps during the dark mornings and overcast days of winter? Slowing down and conserving energy during the cold, barren winters may have given our distant ancestors a survival advantage. To counteract lethargy, National Institute of Mental Health researchers in the early 1980s had an idea: Give people a timed daily dose of intense light. Sure enough, people reported they felt better.

Was light exposure a bright idea, or another dim-witted example of the placebo effect? Research illuminates the issue. One study exposed some people with a seasonal pattern in their depression symptoms to 90 minutes of bright light and others to a sham placebo treatment—a hissing “negative ion generator” about which the staff expressed similar enthusiasm (but which was actually just producing white noise). After four weeks, 61 percent of those exposed to morning light had greatly improved, as had 50 percent of those exposed to evening light and 32 percent of those exposed to the placebo (Eastman et al., 1998).

© Kathryn LeMieux, distributed by King Features Syndicate

Some studies have cast a shadow on light exposure therapy. Nevertheless, others have shown that 30 minutes of morning exposure to 10,000-lux white fluorescent light produces relief for most depressed people. Moreover, it does so as effectively as taking antidepressant drugs or undergoing cognitive-

behavioral therapy (Lam et al., 2006, 2016; Rohan et al., 2007, 2015). Brain scans help explain the benefit: Light therapy sparks activity in a brain region that influences the body's arousal and hormone levels (Ishida et al., 2005).

Christine Brune

Light therapy

To counteract winter depression, some people spend time each morning exposed to intense light that mimics natural outdoor light. Light boxes are available from health supply and lighting stores.

RETRIEVAL PRACTICE

RP-11 What is evidence-based clinical decision making?

ANSWER: Using this approach, therapists make decisions about treatment based on research evidence, clinical expertise, and knowledge of the client.

RP-12 Which alternative psychotherapy has shown more promise as an authentic treatment—EMDR or light therapy?

ANSWER: light therapy

How Do Psychotherapies Help People?

LOQ 16-11 What three elements are shared by all forms of psychotherapy?

Why have studies found little correlation between therapists' training and experience and clients' outcomes? The answer seems to be that all psychotherapies share three basic benefits (Frank, 1982; Wampold, 2007):

- ***Hope for demoralized people*** People seeking therapy typically feel anxious, depressed, self-disapproving, and incapable of turning things around. What any psychotherapy offers is the expectation that, with commitment from the therapy seeker, things can and will get better. This belief, apart from any therapeutic technique, may improve morale, create feelings of self-efficacy, and diminish symptoms (Corrigan, 2014; Meyerhoff & Rohan, 2016).
- ***A new perspective*** Every therapy offers people a plausible explanation of their symptoms. Armed with a believable fresh perspective, they may approach life with a new attitude, open to making changes in their behaviors and their views of themselves.
- ***An empathic, trusting, caring relationship*** To say that therapy outcome is unrelated to training and experience is not to say all *therapists* are equally effective. No matter what technique they use, effective therapists are empathic. They seek to understand the client's experience. They communicate care and concern, and they earn trust through respectful listening, reassurance, and guidance. These qualities were clear in recorded therapy sessions from 36 recognized master therapists (Goldfried et al., 1998). Some took a cognitive-behavioral approach. Others used psychodynamic principles. Regardless, the striking finding was how *similar* they were. At key moments, the empathic therapists of both persuasions would help clients evaluate themselves, link one aspect of their life with another, and gain insight into their interactions with others. The emotional bond between therapist and client—the [therapeutic alliance](#)—helps explain why empathic, caring therapists are especially effective (Klein et al., 2003; Wampold, 2001).

therapeutic alliance a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem.

Mort Gerberg

"The thing is, you have to really want to change."

Mort Gerberg The New Yorker Collection/
The Cartoon Bank

These three common elements—hope, a fresh perspective, and an empathic, caring relationship—help us understand why *paraprofessionals* (briefly trained caregivers, who may be recovered former clients) can assist many troubled people so effectively (Bryan & Arkowitz, 2015; Christensen & Jacobson, 1994). They are also part of what the growing numbers of self-help and support groups offer their members. And they are part of what traditional healers have offered (Jackson, 1992). Healers everywhere—special people to whom others disclose their suffering, whether psychiatrists, witch doctors, or shamans—have listened in order to understand and to empathize, reassure, advise, console, interpret, or explain (Torrey, 1986). Such qualities may explain why people who feel supported by close relationships—who enjoy the fellowship and friendship of caring people—have been less likely to need or seek therapy (Frank, 1982; O'Connor & Brown, 1984).

* * *

To recap, people who seek help usually improve. So do many of those who do not undergo psychotherapy, and that is a tribute to our human resourcefulness and our capacity to care for one another. Nevertheless, though the therapist's orientation and experience appear not to matter much, people who receive some psychotherapy usually improve more than those who do not. People with clear-cut, specific problems tend to improve the most.

RETRIEVAL PRACTICE

RP-13 Those who undergo psychotherapy are _____
(more/less) likely to show improvement than those who do
not undergo psychotherapy.

ANSWER: more

Culture and Values in Psychotherapy

LOQ 16-12 How do culture and values influence the therapist-client relationship?

All psychotherapies offer hope, and nearly all psychotherapists attempt to enhance their clients' sensitivity, openness, personal responsibility, and sense of purpose (Jensen & Bergin, 1988). But in matters of culture and values, psychotherapists differ from one another and may differ from their clients (Delaney et al., 2007; Kelly, 1990).

These differences can create a mismatch when a therapist from one culture interacts with a client from another. In North America, Europe, and Australia, for example, most psychotherapists reflect their culture's *individualism*, which often gives priority to personal desires and identity. Clients with a *collectivist* perspective, as with many from Asian cultures, may assume people will be more mindful of social and family responsibilities, harmony, and group goals. These clients may have trouble relating to therapies that require them to think only of their own well-being (Markus & Kitayama, 1991).

Cultural differences help explain some groups' reluctance to use mental health services. People living in "cultures of honor" prize being strong and tough. They may feel that seeking mental health care is an admission of weakness rather than an opportunity for growth (Brown et al., 2014). And some minority groups tend to be both reluctant to seek therapy and quick to leave it (Chen et al., 2009; Sue et al., 2009). In one experiment, Asian-American clients matched with counselors who shared their cultural values (rather than mismatched with those who did not) perceived more counselor empathy and felt a stronger alliance with the counselor (Kim et al., 2005).

Client-psychotherapist mismatches may also stem from religious values. Highly religious people may prefer and benefit from religiously similar therapists, and may have trouble forming an emotional bond with one who does not share their values (Masters, 2010; Pearce et al., 2015).

Finding a Mental Health Professional

LOQ 16-13 What should a person look for when selecting a psychotherapist?

Life for everyone is marked by a mix of serenity and stress, blessing and bereavement, good moods and bad. So, when should we seek a mental health professional's help? The American Psychological Association offers these common trouble signals:

- Feelings of hopelessness
- Deep and lasting depression
- Self-destructive behavior, such as substance abuse
- Disruptive fears
- Sudden mood shifts
- Thoughts of suicide
- Compulsive rituals, such as hand washing
- Sexual difficulties
- Hearing voices or seeing things that others don't experience

In looking for a psychotherapist, you may want to have a preliminary consultation with two or three. College health centers are generally good starting points and may offer some free services. In the preliminary meetings, you can describe your problem and learn each therapist's treatment approach. You can ask questions about the therapist's values, credentials ([TABLE 16.3](#)), and fees. And you can assess your own feelings about each of them. The emotional bond between therapist and client is perhaps the most important factor in effective therapy.

TABLE 16.3

Therapists and Their Training

Type	Therapy Description
<i>Clinical psychologists</i>	Most are psychologists with a Ph.D. (includes research training) or Psy.D. (focuses on therapy) supplemented by a supervised internship and, often, post-doctoral training. About half work in agencies and institutions, half in private practice.
<i>Psychiatrists</i>	Psychiatrists are physicians who specialize in the treatment of psychological disorders. Not all psychiatrists have had extensive training in psychotherapy, but as M.D.s or D.O.s they can prescribe medications. Thus, they tend to see those with the most serious problems. Many have their own private practice.
<i>Clinical or psychiatric social workers</i>	A two-year master of social work graduate program plus postgraduate supervision prepares some social workers to offer psychotherapy, mostly to people with everyday personal and family problems. About half have earned the National Association of Social Workers' designation of clinical social worker.
<i>Counselors</i>	Marriage and family counselors specialize in problems arising from family relations. Clergy provide counseling to countless people. Abuse counselors work with substance abusers and with spouse and child abusers and their victims. Mental health and other counselors may be required to have a two-year master's degree.

The American Psychological Association recognizes the importance of a strong therapeutic alliance and it welcomes diverse therapists who can relate well to diverse clients. It accredits programs that provide training in cultural sensitivity (for example, to differing values, communication styles, and language) and that recruit underrepresented cultural groups.

REVIEW Evaluating Psychotherapies

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

[therapeutic alliance](#), p. 631

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

The most enthusiastic or optimistic view of the effectiveness of psychotherapy comes from

- a. outcome research.
- b. randomized clinical trials.
- c. reports of clinicians and clients.
- d. a government study of treatment for depression.

Studies show that _____ therapy is the most effective treatment for most psychological disorders.

- a. behavior
- b. humanistic
- c. psychodynamic
- d. no one type of

What are the three components of evidence-based practice?

How does the placebo effect bias patients' attitudes about the effectiveness of various therapies?

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Use  **LearningCurve** to create your personalized study plan, which will direct you to the Macmillan resources that will help you most.

The Biomedical Therapies and Preventing Psychological Disorders

Psychotherapy is one way to treat psychological disorders. The other is *biomedical therapy*. Biomedical treatments can change the brain's chemistry with drugs; affect its circuitry with electrical stimulation, magnetic impulses, or psychosurgery; or influence its responses with lifestyle changes.

Are you surprised to find *lifestyle changes* in this list? We find it convenient to talk of separate psychological and biological influences, but everything psychological is also biological. Some psychologists consider even psychotherapy to be a biological treatment, because changing the way we think and behave is a brain-changing experience (Kandel, 2013). When psychotherapy relieves behaviors associated with obsessive-compulsive disorder or schizophrenia, PET scans reveal a calmer brain (Habel et al., 2010; Schwartz et al., 1996).

“No twisted thought without a twisted molecule.”

Attributed to psychologist Ralph Gerard

Every thought and feeling depends on the functioning brain. Every creative idea, every moment of joy or anger, every period of depression emerges from the electrochemical activity of the living brain. Anxiety disorders, obsessive-compulsive disorder, posttraumatic stress disorder, major depressive disorder, bipolar disorder, and schizophrenia are all biological events. As we have seen over and over, *a human being is an integrated biopsychosocial system*. Thus, our lifestyle—our exercise, nutrition, relationships, recreation, relaxation, religious or spiritual engagement—affects our mental health (Schuch et al., 2016b; Walsh, 2011). (See [Thinking Critically About: Therapeutic Lifestyle Change](#).)

Thinking Critically About: Therapeutic Lifestyle Change

LOQ 16-14 Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

LIFESTYLE
(exercise, nutrition, relationships, recreation, relaxation, and religious or spiritual engagement)

→ **influences our BRAIN AND BODY** → **affects our MENTAL HEALTH**¹

We were designed for physical activity and social engagement.

Our ancestors hunted, gathered, and built in groups.

Modern researchers have found that outdoor activity in a natural environment reduces stress and promotes health.²

APPLICATION TO THERAPY

Training seminars promote therapeutic lifestyle change.³ Small groups of people with depression undergo a 12-week training program with the following goals:

Aerobic exercise, 30 minutes a day, at least three times weekly (increases fitness and vitality, stimulates endorphins)

Regular aerobic exercise rivals the healing power of antidepressant drugs.⁴

Adequate sleep, with a goal of 7 to 8 hours per night (increases energy and alertness, boosts immunity)

A complete night's sleep improves mood and energy.⁵

Light exposure, 15 to 30 minutes each morning with a light box (amplifies arousal, influences hormones)

Social connection, with less alone time and at least two meaningful social engagements weekly (helps satisfy the human need to belong)

Reducing rumination, by identifying and redirecting negative thoughts (enhances positive thinking)

Nutritional supplements, including a daily fish oil supplement with omega-3 fatty acids (aids in healthy brain functioning)

Initial small study (74 participants)⁶

77% of those who completed the program experienced relief from depressive symptoms.

Only 19% of those assigned to a treatment-as-usual control group showed similar results.

Future research will try to identify which parts of the treatment produce the therapeutic effect.

The biomedical therapies assume that mind and body are a unit:
Affect one and you will affect the other.

RETRIEVAL PRACTICE

RP-14 What are some examples of lifestyle changes we can make to enhance our mental health?

ANSWER: Exercise regularly, get enough sleep, get more exposure to light (get outside and/or use a light box), nurture important relationships, redirect negative thinking, and eat a diet rich in omega-3 fatty acids.

Drug Therapies

LOQ 16-15 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

By far the most widely used biomedical treatments today are the drug

therapies. Most drugs for anxiety and depression are prescribed by primary care providers, followed by psychiatrists and, in some states, psychologists.

Since the 1950s, discoveries in [psychopharmacology](#) (the study of drug effects on mind and behavior) have revolutionized the treatment of people with severe disorders, liberating hundreds of thousands from hospital confinement. Thanks to drug therapy and local community mental health programs, the resident population of U.S. state and county mental hospitals is now a small fraction of what it was in the mid-twentieth century. For some who are unable to care for themselves, however, release from hospitals has meant homelessness, not liberation.

psychopharmacology the study of the effects of drugs on mind and behavior.

Edward Koren The New Yorker Collection/The Cartoon Bank

"Our psychopharmacologist is a genius."

Almost any new treatment, including drug therapy, is greeted by an initial wave of enthusiasm as many people apparently improve. But that enthusiasm often diminishes on closer examination. To evaluate the effectiveness of any new drug, researchers also need to know normal recovery rates:

- How many people recover without treatment, and how quickly?

- Is recovery due to the drug or to the *placebo effect*? When patients or mental health workers expect positive results, they may see what they expect, not what really happens. Even mere exposure to advertising about a drug's supposed effectiveness can increase its effect (Kamenica et al., 2013).

To control for these influences, drug researchers give half the patients the drug, and the other half a similar-appearing placebo. Because neither the staff nor the patients know who gets which, this is called a *double-blind procedure*. The good news: In double-blind studies, several types of drugs effectively treat psychological disorders.

Antipsychotic Drugs

An accidental discovery launched a treatment revolution for people with *psychoses*. The discovery: Certain drugs, used for other medical purposes, calmed the hallucinations or delusions that are part of these patients' split from reality. First-generation [antipsychotic drugs](#), such as chlorpromazine (Thorazine), dampened responsiveness to irrelevant stimuli. Thus, they provided the most help to patients experiencing positive (actively inappropriate) symptoms of schizophrenia, such as auditory hallucinations and paranoia (Lehman et al., 1998; Lenzenweger et al., 1989). (Antipsychotic drugs are not equally effective in changing negative symptoms such as apathy and withdrawal.)

antipsychotic drugs drugs used to treat schizophrenia and other forms of severe thought disorder.

The molecules of most conventional antipsychotic drugs are similar enough to molecules of the neurotransmitter dopamine to occupy its receptor sites and block its activity. This finding reinforces the idea that an overactive dopamine system contributes to schizophrenia.

Perhaps you can guess an occasional side effect of L-dopa, a drug that raises dopamine levels for Parkinson's patients: hallucinations.

Antipsychotics also have powerful side effects. Some produce sluggishness, tremors, and twitches similar to those of Parkinson's disease (Kaplan & Saddock, 1989). Long-term use of antipsychotics can produce *tardive dyskinesia*, with involuntary movements of the facial muscles (such as grimacing), tongue, and limbs. Although not more effective in controlling schizophrenia symptoms, many of the newer-generation antipsychotics, such as risperidone (Risperdal) and olanzapine (Zyprexa), work best for those with severe symptoms and have fewer of these effects (Furukawa et al., 2015). These drugs may, however, increase the risk of obesity and diabetes (Buchanan et al., 2010; Tiihonen et al., 2009).

Antipsychotics, combined with life-skills programs and family support, have given new hope to many people with schizophrenia (Guo et al., 2010). Hundreds of thousands of patients have left the wards of mental hospitals and returned to work and to near-normal lives (Leucht et al., 2003). Elyn Saks (2007), a University of Southern California law professor, knows what it means to live with schizophrenia. Thanks to her treatment, which combines an antipsychotic drug and psychotherapy, she noted, "Now I'm mostly well. I'm mostly thinking clearly. I do have episodes, but it's not like I'm struggling all of the time to stay on the right side of the line."

Antianxiety Drugs

Like alcohol, [antianxiety drugs](#), such as Xanax or Ativan, depress central nervous system activity (and so should not be used in combination with alcohol). Some antianxiety drugs have been successfully used in combination with psychological therapy to enhance exposure therapy's extinction of learned fears and to help relieve the symptoms of posttraumatic stress disorder and obsessive-compulsive disorder (Davis, 2005; Kushner et al., 2007).

antianxiety drugs drugs used to control anxiety and agitation.

Some critics fear that antianxiety drugs may reduce symptoms without

resolving underlying problems, especially when used as an ongoing treatment. “Popping a Xanax” at the first sign of tension can create a learned response: The immediate relief reinforces a person’s tendency to take drugs when anxious. Antianxiety drugs can also be addictive. Regular users who stop taking these drugs may experience increased anxiety, insomnia, and other withdrawal symptoms.

Antidepressant Drugs

The [antidepressant drugs](#) were named for their ability to lift people up from a state of depression, and this was their main use until recently. The label is a bit of a misnomer now that these drugs are increasingly used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder (Wetherell et al., 2013). Many work by increasing the availability of neurotransmitters, such as norepinephrine or serotonin, which elevate arousal and mood and are scarce when a person experiences feelings of depression or anxiety. The most commonly prescribed drugs in this group, including Prozac and its cousins Zoloft and Paxil, work by prolonging the time serotonin molecules remain in the brain’s synapses. They do this by partially blocking the normal reuptake process ([FIGURE 16.5](#)). Given their use in treating disorders other than depression—from anxiety to strokes—these drugs are most often called *SSRIs*—*selective serotonin reuptake inhibitors* (rather than antidepressants) (Kramer, 2011).

antidepressant drugs drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—*SSRIs*.)

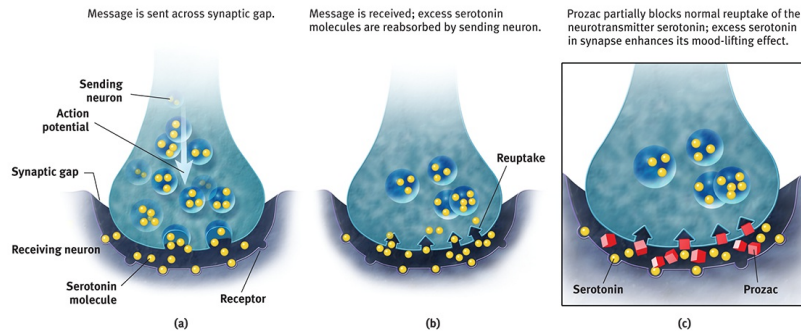

FIGURE 16.5 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 16.5 Biology of antidepressants

Shown here is the action of Prozac, which partially blocks the reuptake of serotonin.

Some of the older antidepressant drugs work by blocking the reabsorption or breakdown of both norepinephrine and serotonin. Though effective, these dual-action drugs have more potential side effects, such as dry mouth, weight gain, hypertension, or dizzy spells (Anderson, 2000; Mulrow, 1999). Administering them by means of a patch, which bypasses the intestines and liver, helps reduce such side effects (Bodkin & Amsterdam, 2002). Some professionals prefer the SSRIs over other antidepressants (Jakubovski et al., 2015; Kramer, 2011).

But be advised: Patients with depression who begin taking antidepressants do not wake up the next day singing, “It’s a beautiful day!” SSRIs begin to influence neurotransmission within hours, but their full psychological effect may take four weeks (and may involve a side effect of diminished sexual desire). One possible reason for the delay is that increased serotonin promotes new synapses plus *neurogenesis*—the birth of new brain cells—perhaps reversing stress-induced loss of neurons (Launay et al., 2011). Researchers are also exploring the possibility of quicker-acting antidepressants. One, ketamine, which is also an anesthetic and a party drug, blocks hyperactive receptors for glutamate, a neurotransmitter, and causes a burst of new synapses. It can provide relief from depression within hours of an infusion, often after transient hallucinations (Grimm & Scheidegger, 2013; McGirr et al., 2015; Naughton et al., 2014). But the relief often dissipates in a week (Kishimoto et al., 2016). Some drug companies are hoping to develop a ketamine-like, fast-acting drug without its side effects (Kirby, 2015).

Antidepressant drugs are not the only way to give the body a lift. Aerobic exercise can calm people who feel anxious, energize those who feel

depressed, and offer other positive side effects. Cognitive therapy, by helping people reverse their habitual negative thinking style, can boost drug-aided relief from depression and reduce posttreatment relapses (Amick et al., 2015). Some clinicians attack depression (and anxiety) from both below and above (Cuijpers et al., 2010; Hollon et al., 2014; Kennard et al., 2014): They use antidepressant drugs (which work, bottom-up, on the emotion-forming limbic system) in conjunction with cognitive-behavioral therapy (which works, top-down, to alter frontal lobe activity and change thought processes).

"If this doesn't help you don't worry, it's a placebo."

Peter C. Vey/The New Yorker Collection.
cartoonbank.com

Researchers generally agree that people with depression often improve after a month on antidepressant drugs. But after allowing for natural recovery and the placebo effect, how big is the drug effect? Not big, report some researchers (Kirsch et al., 1998, 2014, 2016). In double-blind clinical trials, placebos produced improvement comparable to about 75 percent of the active drug's effect. For those with severe depression, the placebo effect is less and the added drug benefit somewhat greater (Fournier et al., 2010; Kirsch et al., 2008; Olfson & Marcus, 2009). Given that antidepressants often have unwanted side effects, and that aerobic exercise and cognitive behavioral therapy are also effective antidotes to mild or moderate depression, Irving Kirsch (2016) recommends more limited antidepressant use: "If they are to be used at all, it should be as a last resort."

To better understand how clinical researchers have explored these questions, engage online with **How Would You Know How Well Antidepressants Work?**

Mood-Stabilizing Medications

In addition to antipsychotic, antianxiety, and antidepressant drugs, psychiatrists have *mood-stabilizing drugs* in their arsenal. One of them, Depakote, was originally used to treat epilepsy. It was also found effective in controlling the manic episodes associated with bipolar disorder. Another, the simple salt *lithium*, effectively levels the emotional highs and lows of this disorder.

The New Yorker Collection, 2000, P.C. Vey from cartoonbank.com. All Rights Reserved.

"First of all I think you should know that last quarter's sales figures are interfering with my mood-stabilizing drugs."

Australian physician John Cade discovered the benefits of lithium in the 1940s when he administered it to a patient with severe mania and the patient became well in less than a week (Snyder, 1986). About 7 in 10 people with bipolar disorder benefit from a long-term daily dose of this cheap salt, which helps prevent or ease manic episodes and, to a lesser extent, lifts depression (Solomon et al., 1995). Kay Redfield Jamison (1995, pp. 88–89) described the effect:

Lithium prevents my seductive but disastrous highs, diminishes my depressions, clears out the wool and webbing from my disordered thinking, slows me down, gentles me out, keeps me from ruining my career and relationships, keeps me out of a hospital, alive, and makes psychotherapy possible.

Taking lithium also correlates with a lower risk of suicide among people with bipolar disorder—to about one-sixth the risk of those not taking lithium (Oquendo et al., 2011). Naturally occurring lithium in drinking water has also correlated with lower suicide rates (across 18 Japanese cities and towns) and lower crime rates (across 27 Texas counties) (Ohgami et al., 2009; Schrauzer

& Shrestha, 1990, 2010; Terao et al., 2010). Lithium works.

RETRIEVAL PRACTICE

RP-15 How do researchers determine if particular drug therapies are effective?

ANSWER: Researchers assign people to treatment and no-treatment conditions to see if those who receive the drug therapy improve more than those who don't. Double-blind controlled studies are most effective. If neither the therapist nor the client knows which participants have received the drug treatment, then any difference between the treated and untreated groups will reflect the drug treatment's actual effect.

RP-16 The drugs given most often to treat depression are called _____. Schizophrenia is often treated with _____ drugs.

ANSWER: antidepressants; antipsychotic

Brain Stimulation

LOQ 16-16 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive Therapy

Another biomedical treatment, [electroconvulsive therapy \(ECT\)](#), manipulates the brain by shocking it. When ECT was first introduced in 1938, the wide-awake patient was strapped to a table and jolted with electricity to the brain. The procedure, which produced convulsions and brief unconsciousness, gained a barbaric image. Although that image lingers, today's ECT is much kinder and gentler, and no longer "convulsive." The patient receives a general anesthetic and a muscle relaxant (to prevent bodily convulsions). A

psychiatrist then delivers a brief pulse of electrical current, sometimes only to the brain's right side, which triggers a 30- to 60-second seizure (McCall et al., 2017). Within 30 minutes, the patient awakens and remembers nothing of the treatment or of the preceding hours.

electroconvulsive therapy (ECT) a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient.

Study after study confirms that ECT can effectively treat severe depression in “treatment-resistant” patients who have not responded to drug therapy (Bailine et al., 2010; Fink, 2009; Lima et al., 2013; Medda et al., 2015). After three such sessions each week for two to four weeks, 70 percent or more of those receiving today's ECT improve markedly, without discernible brain damage and with less memory loss than with earlier versions of ECT (HMH, 2007). ECT also reduces suicidal thoughts and has been credited with saving many from suicide (Kellner et al., 2006). A *Journal of the American Medical Association* editorial concluded that “the results of ECT in treating severe depression are among the most positive treatment effects in all of medicine” (Glass, 2001).

How does ECT alleviate severe depression? After more than 70 years, no one knows for sure. One recipient likened ECT to the smallpox vaccine, which was saving lives before we knew how it worked. Perhaps the brief electric current calms neural centers where overactivity produces depression. Some research indicates that ECT stimulates neurogenesis (new neurons) and new synaptic connections within the hippocampus and amygdala (Joshi et al., 2016; Rotheneichner et al., 2014).

The medical use of electricity is an ancient practice. Physicians treated the Roman Emperor Claudius (10 B.C.E.–54 C.E.) for headaches by pressing electric eels to his temples. Today, about 17 people per 100,000—people whose depression has not responded to other treatments—have received ECT (Lesage et al., 2016).

No matter how impressive the results, the idea of electrically shocking a person's brain still strikes many as barbaric, especially given our ignorance about why ECT works. Moreover, the mood boost may not last long. Many ECT-treated patients eventually relapse back into depression, although relapses are somewhat fewer for those receiving antidepressant drugs or who do aerobic exercise (Rosenquist et al., 2016; Salehi et al., 2016). *The bottom line:* In the minds of many psychiatrists and patients, ECT is a lesser evil than severe depression's misery, anguish, and risk of suicide. As research psychologist Norman Endler (1982) reported after ECT alleviated his deep depression, "A miracle had happened in two weeks."

Alternative Neurostimulation Therapies

Three other neural stimulation techniques—mild cranial electrical stimulation, magnetic stimulation, and deep-brain stimulation—also aim to treat the depressed brain ([FIGURE 16.6](#)).

FIGURE 16.6 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE 16.6 A stimulating experience

Today's neurostimulation therapies apply strong or mild electricity, or magnetic energy, either to the skull's surface or directly to brain neurons.

TRANSCRANIAL ELECTRICAL STIMULATION In contrast to ECT, which produces a brain seizure with about 800 milliamps of electricity, *transcranial direct current stimulation* (tDCS) administers a weak 1- to 2-milliamp current to the scalp. The current is so mild that some people have attempted to use tDCS machines to stimulate their own cognitive abilities, though skeptics argue that such a current is too weak to penetrate to the brain and that studies do not confirm cognitive benefits (Horvath et al., 2015; Underwood, 2016). After reviewing recent studies, two European expert

panels did, however, report “probable efficacy” of tDCS as a depression treatment (Brunoni et al., 2016; Lefaucheur et al., 2017).

MAGNETIC STIMULATION Depressed moods also sometimes improve when a painless procedure—called [repetitive transcranial magnetic stimulation \(rTMS\)](#)—is performed on wide-awake patients over several weeks. Repeated pulses surging through a magnetic coil held close to the skull can stimulate or suppress activity in areas of the cortex. Like tDCS (and unlike ECT), the rTMS procedure produces no memory loss or other serious side effects, aside from possible headaches.

repetitive transcranial magnetic stimulation (rTMS) the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity.

A meta-analysis of 17 clinical experiments found that one other stimulation procedure alleviates depression: massage therapy (Hou et al., 2010).

Some studies have found that, for 30 to 40 percent of people with depression, rTMS works (Becker et al., 2016; Brunoni et al., 2017; Taylor et al., 2017). How it works is unclear. One possible explanation is that the stimulation energizes the brain’s left frontal lobe, which is relatively inactive during depression (Helmuth, 2001). Repeated stimulation may cause nerve cells to form new functioning circuits through the process of *long-term potentiation*. More research will shed light on how rTMS works, and for whom.

DEEP-BRAIN STIMULATION Other patients whose depression has resisted both drugs and ECT have benefited from an experimental treatment pinpointing a neural hub that bridges the thinking frontal lobes to the limbic system (Becker et al., 2016; Brunoni et al., 2017; Ryder & Holtzheimer, 2016). This area, which is overactive in the brain of a depressed or temporarily sad person, calms when treated by ECT or antidepressants. To experimentally activate neurons that inhibit this negative activity,

neuroscientist Helen Mayberg drew upon *deep-brain stimulation* (DBS) technology, sometimes used to treat Parkinson’s tremors. Since 2003, she and her colleagues have used DBS to treat some 200 depressed patients via implanted electrodes in a brain area that functions as the neural “sadness center” (Lozano & Mayberg, 2015). About one-third reportedly have responded “extremely well” and another 30 percent have modestly improved (Underwood, 2013). Some felt suddenly more aware and became more talkative and engaged; others improved only slightly, if at all. Other studies have found little benefit when DBS is compared to “sham” (placebo) electrode treatments (Witter & Ward, 2016). Future research will explore whether Mayberg has discovered a switch that can lift depression.

Helen Mayberg, M.D. Psychiatric Neuroimaging and Therapeutics, The Mayberg Lab at Emory University, Atlanta, GA/V. J. Wedeen and L. L. Wald/Athinoula A. Martinos Center For Biomedical Imaging and The Human Connectome Project, Boston, MA

A depression switch?

By comparing the brains of patients with and without depression, researcher Helen Mayberg identified a brain area (highlighted in red) that appears active in people who are depressed or sad, and whose activity may be calmed by deep-brain stimulation.

Psychosurgery

Because its effects are irreversible, [psychosurgery](#)—surgery that removes or destroys brain tissue—is the most drastic and least-used biomedical intervention for changing behavior. In the 1930s, Portuguese physician Egas Moniz developed what would become the best-known psychosurgical operation: the [lobotomy](#). Moniz found that cutting the nerves connecting the frontal lobes with the emotion-controlling centers of the inner brain calmed uncontrollably emotional and violent patients. In what would later become, in

others' hands, a crude but quick and easy procedure, a neurosurgeon would shock the patient into a coma, hammer an icepick-like instrument through each eye socket into the brain, and then wiggle it to sever connections running up to the frontal lobes. Between 1936 and 1954, tens of thousands of severely disturbed people were “lobotomized” (Valenstein, 1986).

psychosurgery surgery that removes or destroys brain tissue in an effort to change behavior.

lobotomy a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain.

Although the intention was simply to disconnect emotion from thought, the effect was often more drastic. A lobotomy usually decreased the person's misery or tension, but also produced a permanently lethargic, immature, uncreative person. During the 1950s, after some 35,000 people had been lobotomized in the United States alone, calming drugs became available and psychosurgery became scorned, as in the saying sometimes attributed to W. C. Fields that “I'd rather have a bottle in front of me than a frontal lobotomy.”

Today, lobotomies are history. More precise, microscale psychosurgery is sometimes used in extreme cases. For example, if a patient suffers uncontrollable seizures, surgeons can deactivate the specific nerve clusters that cause or transmit the convulsions. MRI-guided precision surgery is also occasionally done to cut the circuits involved in severe obsessive-compulsive disorder (Carey, 2009, 2011; Sachdev & Sachdev, 1997). Because these procedures are irreversible, neurosurgeons perform them only as a last resort.

New York Times Co./Getty Images

Failed lobotomy

This 1940 photo shows Rosemary Kennedy (center) at age 22 with brother (and future U.S. president) John and sister Jean. A year later her father, on medical advice, approved a lobotomy that was promised to control her reportedly violent mood swings. The procedure left her confined to a hospital with an infantile mentality until her death in 2005 at age 86.

RETRIEVAL PRACTICE

RP-17 Severe depression that has not responded to other therapy may be treated with _____, which can cause brain seizures and memory loss. More moderate neural stimulation techniques designed to help alleviate depression include _____ direct current stimulation, _____ magnetic stimulation, and _____ - _____ stimulation.

ANSWER: electroconvulsive therapy; transcranial; repetitive

transcranial; deep-brain

* * *

TABLE 16.4 summarizes some aspects of the biomedical therapies we've discussed.

TABLE 16.4
Comparing Biomedical Therapies

Therapy	Presumed Problem	Therapy Aim	Therapy Technique
<i>Therapeutic lifestyle change</i>	Stress and unhealthy lifestyle	Restore healthy biological state.	Alter lifestyle through adequate exercise, sleep, nutrition, and other changes.
<i>Drug therapies</i>	Neurotransmitter malfunction	Control symptoms of psychological disorders.	Alter brain chemistry through drugs.
<i>Brain stimulation</i>	Depression (ECT is used only for severe, treatment-resistant depression.)	Alleviate depression, especially when it is unresponsive to drugs or other forms of therapy.	Stimulate brain through electroconvulsive shock, mild electrical stimulation, magnetic impulses, or deep-brain stimulation.
<i>Psychosurgery</i>	Brain malfunction	Relieve severe	Remove or destroy brain tissue.

		disorders.

Preventing Psychological Disorders and Building Resilience

LOQ 16-17 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

Psychotherapies and biomedical therapies tend to locate the cause of psychological disorders within the person. We infer that people who act cruelly must be cruel and that people who act “crazy” must be “sick.” We attach labels to such people, thereby distinguishing them from “normal” folks. It follows, then, that we try to treat “abnormal” people by giving them insight into their problems, by changing their thinking, by helping them gain control with drugs.

Dave Coverly/Speed Bump

There is an alternative viewpoint: We could interpret many psychological disorders as understandable responses to a disturbing and stressful society. According to this view, it is not just the person who needs treatment, but also the person’s social context. Better to prevent a problem by reforming a sick situation and by developing people’s coping competencies than to wait for

and treat problems.

Preventive Mental Health

A story about the rescue of a drowning person from a rushing river illustrates this viewpoint: Having successfully administered first aid to the first victim, the rescuer spots another struggling person and pulls her out, too. After a half-dozen repetitions, the rescuer suddenly turns and starts running away while the river sweeps yet another floundering person into view. “Aren’t you going to rescue that fellow?” asks a bystander. “Heck no,” the rescuer replies. “I’m going upstream to find out what’s pushing all these people in.”

“It is better to prevent than to cure.”

Peruvian folk wisdom

Preventive mental health is upstream work. It seeks to prevent psychological casualties by identifying and alleviating the conditions that cause them. As George Albee (1986, 2006) pointed out, there is abundant evidence that poverty, meaningless work, constant criticism, unemployment, racism, and sexism undermine people’s sense of competence, personal control, and self-esteem. Such stresses increase their risk of depression, alcohol use disorder, and suicide.

To prevent psychological casualties we should, Albee contended, support programs that alleviate these demoralizing situations. We eliminated smallpox not by treating the afflicted but by inoculating the unafflicted. We conquered yellow fever by controlling mosquitoes. Better to drain the swamps than swat the mosquitoes.

Preventing psychological problems means empowering those who have learned an attitude of helplessness and changing environments that breed loneliness. It means renewing fragile family ties and boosting parents’ and teachers’ skills at nurturing children’s competence and belief in their abilities. It means harnessing positive psychology interventions to enhance human flourishing. In short, “everything aimed at improving the human condition, at making life more fulfilling and meaningful, may be considered part of primary prevention of mental or emotional disturbance” (Kessler & Albee,

1975, [p. 557](#)). Prevention can sometimes provide a double payoff. People with a strong sense of life's meaning are more engaging socially (Stillman et al., 2011). If we can strengthen people's sense of meaning in life, we may also lessen their loneliness as they grow into more engaging companions.

Among the upstream prevention workers are *community psychologists*. Mindful of how people interact with their environment, they focus on creating environments that support psychological health. Through their research and social action, community psychologists aim to empower people and to enhance their competence, health, and well-being.

“Mental disorders arise from physical ones, and likewise physical disorders arise from mental ones.”

The Mahabharata, 200 B.C.E.

Building Resilience

Preventive mental health includes efforts to build individuals' [resilience](#)—the ability to cope with stress and recover from adversity.

resilience the personal strength that helps most people cope with stress and recover from adversity and even trauma.

Faced with unforeseen trauma, most adults exhibit resilience. This was true of New Yorkers in the aftermath of the September 11 terror attacks, especially those who enjoyed supportive close relationships and who had not recently experienced other stressful events (Bonanno et al., 2007). More than 9 in 10 New Yorkers, although stunned and grief-stricken by 9/11, did *not* have a dysfunctional stress reaction. Among those who did, the stress symptoms were mostly gone by the following January (Person et al., 2006). Even most combat-stressed veterans, most political rebels who have survived torture, and most people with spinal cord injuries do not later exhibit posttraumatic stress disorder (Bonanno et al., 2012; Mineka & Zinbarg, 1996).

Struggling with challenging crises can even lead to [posttraumatic growth](#). Many cancer survivors have reported a greater appreciation for life, more meaningful relationships, increased personal strength, changed priorities, and a richer spiritual life (Tedeschi & Calhoun, 2004). Americans who tried to make sense of the 9/11 terror attacks experienced less distress (Park et al., 2012). Out of even our worst experiences, some good can come, especially when we can imagine new possibilities (Roepke, 2015; Roepke & Seligman, 2015). Suffering can beget new sensitivity and strength.

posttraumatic growth positive psychological changes as a result of struggling with extremely challenging circumstances and life crises.

RETRIEVAL PRACTICE

RP-18 What is the difference between preventive mental health and the psychological and biomedical therapies?

ANSWER: Psychological and biomedical therapies attempt to relieve people's suffering from psychological disorders. Preventive mental health attempts to prevent suffering by identifying and eliminating the conditions that cause disorders.

* * *

If you just finished reading this book, your introduction to psychological science is completed. Our tour of psychological science has taught us much—and you, too?—about our moods and memories, about the reach of our unconscious, about how we flourish and struggle, about how we perceive our physical and social worlds, and about how our biology and culture shape us. Our hope, as your guides on this tour, is that you have shared some of our fascination, grown in your understanding and compassion, and sharpened your critical thinking. And we hope you enjoyed the ride.

With every good wish in your future endeavors,

David G. Myers

[posttraumatic growth](#), p. 643

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

Some antipsychotic drugs, used to calm people with schizophrenia, can have unpleasant side effects, most notably

- a. hyperactivity.
- b. convulsions and momentary memory loss.
- c. sluggishness, tremors, and twitches.
- d. paranoia.

Drugs such as Xanax and Ativan, which depress central nervous system activity, can become addictive when used as ongoing treatment. These drugs are referred to as _____ drugs.

A simple salt that often brings relief to patients suffering the highs and lows of bipolar disorder is _____.

When drug therapies have not been effective, electroconvulsive therapy (ECT) may be used as treatment, largely for people with

- a. severe obsessive-compulsive disorder.
- b. severe depression.
- c. schizophrenia.
- d. anxiety disorders.

An approach that seeks to identify and alleviate conditions that put people at high risk for developing psychological disorders is called

- a. deep-brain stimulation.
- b. the mood-stabilizing perspective.
- c. spontaneous recovery.
- d. preventive mental health.

Answers are a click away in the e-book, and available in [Appendix D](#) at the back of the printed text.

Use  LearningCurve to create your personalized study plan, which will direct you to the Macmillan resources that will help you most.

Endnotes

Appendix B: Career Fields in Psychology

[1](#) Although this text covers the world of psychology for students in many countries, this appendix draws primarily from available U.S. data. These descriptions of career fields in psychology do, however, apply to many other countries as well.

Chapter 1

¹ Boston is south of Paris.

² The anagram solution: CHAOS.

³ The independent variable, which the researchers manipulated, was the implied ethnicity of the applicants' names. The dependent variable, which researchers measured, was the rate of positive responses from the landlords.

⁴ The actual standard deviation formula: $\frac{\text{Sum of (deviations from mean)}^2}{\text{Number of scores}}$

$$\sqrt{\frac{\text{Sum of (deviations from mean)}^2}{\text{Number of scores}}}$$

Chapter 3

¹ So, would the reverse damage lead to the opposite symptoms? Indeed, there are a few such patients—who can see and recognize objects but have difficulty pointing toward or grasping them.

² This analogy, adapted here with world-based numbers, was suggested by mathematician Sam Saunders, as reported by K. C. Cole (1998).

Chapter 4

¹ Actually, this description of the two Jims errs in one respect: Jim Lewis named his son James Alan. Jim Springer named his James Allan.

² ANSWERS: (1) males, 58 percent; females, 34 percent. (2) males, 48 percent; females, 12 percent. (3) males, 25 percent; females, 48 percent. (4) males, 54 percent; females, 19 percent. (5) males, 43 percent; females, 25 percent.

Chapter 6

¹ The title's first error is its repeated "The." Its ironic second error is its misstatement that there are two errors, when there is only one.

Chapter 7

¹ The “buzzer” (English translation) was perhaps the bell people commonly associate with Pavlov (Tully, 2003). Pavlov used various stimuli, but some have questioned whether he used a bell.

Chapter 8

¹ One of my cookie-scarfing sons, on reading this in his father's textbook years later, confessed he had fibbed "a little."

² bicycle, void, cigarette, inherent, fire, process.

Chapter 9

¹ Answer to SPLPYOCHYC anagram: PSYCHOLOGY

² The word is *apple*: pineapple, crabapple, applesauce.

³ Tversky and Kahneman's joint work on decision making received a 2002 Nobel Prize; sadly, only Kahneman was alive to receive the honor.

⁴ The first answer is 5 cents. The bat would then cost \$1.05, for a \$1.10 total. If the ball cost the intuitive answer of 10 cents, the bat would then have to cost \$1.10 (for a bat-and-ball total of \$1.20, not \$1.10). The second answer is 5 minutes, because each machine makes a widget every 5 minutes. If you answered incorrectly, don't feel bad—so do most university students (Frederick, 2005).

Chapter 10

¹ The correct answer is c.

Chapter 11

¹ Answer: Figure (c).

² The researchers later *debriefed* and reassured the participants.

Chapter 12

¹ From left to right, top to bottom: happiness, surprise, fear, sadness, anger, disgust.

Chapter 14

¹ We couldn't resist throwing that in. But don't worry, you won't be tested on floccinaucinihilipilification, which is the act of estimating something as worthless (and was the longest nontechnical word in the first edition of the *Oxford English Dictionary*).

Chapter 15

¹ OCD and PTSD were formerly classified as anxiety disorders, but the DSM-5 now classifies them separately.

Human Factors Psychology

For most people, to live is to work. Work is life's biggest waking activity. Work helps satisfy multiple needs. Work supports us, enabling food, water, and shelter. Work connects us, meeting our social needs. Work helps define us. Meeting someone for the first time and wondering about their identity, we may ask, "So, what do you do?"

But the answer may give us only a partial picture of a person's life. We have many motives beyond work, including the desire for family, friends, and hobbies. We also vary in our job satisfaction. On the day we leave the workforce, some of us will sadly bid our former employer farewell; others will bid our former employer good riddance. What factors influence our perceptions of work as an activity marked by frustration versus *flow*, as a necessary chore versus a meaningful calling, or as an opportunity to do the

bare minimum versus maximize our potential?

Work and Life Satisfaction

Flow at Work

LOQ **LEARNING OBJECTIVE QUESTION** **A-1** What is *flow*?

Individuals across various occupations vary in their attitudes toward their work. Some view their work as a *job*, an unfulfilling but necessary way to make money. Others view their work as a *career*, an opportunity to advance from one position to a better position. The rest—those who view their work as a *calling*, a fulfilling and socially useful activity—report the highest satisfaction with their work and with their lives (Dik & Duffy, 2012; Wrzesniewski & Dutton, 2001).

This finding would not surprise Mihaly Csikszentmihalyi [chick-SENT-me-hi] (1990, 1999). He observed that our quality of life increases when we are purposefully engaged. Between the anxiety of being overwhelmed and stressed, and the apathy of being underwhelmed and bored, lies a zone in which we experience **flow**. Can you recall being in a zoned-out flow state while texting or playing a video game? If so, then perhaps you can sympathize with the two Northwest Airlines pilots who in 2009 were so focused on their laptops that they missed their control tower's messages. The pilots flew 150 miles past their Minneapolis destination—and lost their jobs.

flow a completely involved, focused state, with diminished awareness of self and time; results from full engagement of our skills.

The jobs people do: Columnist Gene Weingarten (2002) noted that sometimes a humor writer knows “when to just get out of the way.” Here are some sample job titles from the U.S. Department of Labor *Dictionary of Occupational Titles*: animal impersonator, human projectile, banana ripening-room supervisor, impregnator, impregnator helper, dope sprayer, finger waver, rug scratcher, egg smeller, bottom

buffer, cookie breaker, brain picker, hand pouncer, bosom presser, and mother repairer.

Csikszentmihalyi formulated the flow concept after studying artists who spent hour after hour painting or sculpting with focused concentration. Immersed in a project, they worked as if nothing else mattered, and then, when finished, they promptly forgot about it. The artists seemed driven less by external rewards—money, praise, promotion—than by the intrinsic rewards of creating their art. Nearly 200 other studies confirm that *intrinsic motivation* enhances performance (Cerasoli et al., 2014).

Csikszentmihalyi studied dancers, chess players, surgeons, writers, parents, mountain climbers, sailors, and farmers. His research included Australians, North Americans, Koreans, Japanese, and Italians. Participants ranged in age from the teen years to the golden years. A clear principle emerged: It's exhilarating to flow with an activity that fully engages our skills (Fong et al., 2015). Flow experiences boost our sense of self-esteem, competence, and well-being. Idleness may sound like bliss, but purposeful work enriches our lives. Busy people are happier (Hsee et al., 2010; Robinson & Martin, 2008). One research team interrupted people on about a quarter-million occasions (using a phone app), and found people's mind wandering 47 percent of the time. They were, on average, happier when their mind was *not* wandering (Killingsworth & Gilbert, 2010).

Jacob Ammentorp Lund/Getty Images

Life disrupted

Playing and socializing online are ever-present sources of distraction. It takes energy to resist checking our phones, and time to refocus mental concentration after each disruption. Such frequent interruptions disrupt flow, so it's a good idea to instead schedule regular breaks for checking our handheld devices.

Have you ever noticed that when you are immersed in an activity, time flies? And that when you are watching the clock, it seems to move more slowly? French researchers have confirmed that the more we attend to an event's duration, the longer it seems to last (Couli et al., 2004).

“Find a job you love, and you'll never work another day of your life.”

Facebook hiring video, 2016

Finding Your Own Flow, and Matching Interests to Work

Want to identify your own path to flow? You can start by pinpointing your strengths and the types of work that may prove satisfying and successful. Marcus Buckingham and Donald Clifton (2001) suggested asking yourself four questions.

What activities give me pleasure? Bringing order out of chaos? Playing host? Helping others? Challenging sloppy thinking?

What activities leave me wondering, “When can I do this again?” rather than, “When will this be over?”

What sorts of challenges do I relish? And which do I dread?

What sorts of tasks do I learn easily? And which do I struggle with?

You may find your skills engaged and time flying when teaching or selling or writing or cleaning or consoling or creating or repairing. If an activity feels good, if it comes easily, if you look forward to it, then look deeper. You'll

see your strengths at work (Buckingham, 2007). For a free (requires registration) assessment of your own strengths, take the “Brief Strengths Test” at AuthenticHappiness.sas.upenn.edu.

The U.S. Department of Labor also offers a career interest questionnaire through its Occupational Information Network (O*NET). At MyNextMove.org/explore/ip you will need about 10 minutes to respond to 60 items, indicating how much you would like or dislike activities ranging from building kitchen cabinets to playing a musical instrument. You will then receive feedback on how strongly your responses reflect six interest types (Holland, 1996):

- *Realistic* (hands-on doers)
- *Investigative* (thinkers)
- *Artistic* (creators)
- *Social* (helpers, teachers)
- *Enterprising* (persuaders, deciders)
- *Conventional* (organizers)

Finally, depending on how much training you are willing to complete, you will be shown occupations that fit your interest pattern (selected from a national database of 900+ occupations).

Do what you love and you will love what you do. A career counseling science aims, first, to assess people’s differing values, personalities, and, especially, interests, which are remarkably stable (Dik & Rottinghaus, 2013). (Your job may change, but your interests today will likely still be your interests in 10 years.) Second, it aims to alert people to well-matched vocations—vocations with a good *person-environment fit*. One study assessed 400,000 high school students’ interests and then followed them over time. The take-home finding: “Interests uniquely predict academic and career success over and above cognitive ability and personality” (Rounds & Su, 2014). Sixty other studies confirm the point both for students in school and workers on the job: Interests predict both performance and persistence (Nye et al., 2012). Lack of job fit can fuel frustration, resulting in unproductive and even hostile work behavior (Harold et al., 2016). One fee-based online service, jobzology.com, was developed by I/O psychologists to implement career counseling science. First, it assesses people’s interests, values, personalities, and workplace culture preferences. It then suggests occupations and connects them to job listings.

RETRIEVAL PRACTICE

RP-1 What is the value of finding flow in our work?

ANSWER: We become more likely to view our work as fulfilling and socially useful, and we experience higher self-esteem, feelings of competence, and overall well-being.

Industrial-Organizational Psychology

LOQ A-2 What are three key areas of study related to industrial-organizational psychology?

In developed nations work has expanded, from farming to manufacturing to *knowledge work*. More and more work is *outsourced* to temporary employees and consultants, or to workers telecommuting from off-site workplaces (Allen, T. D., et al., 2015). (This book and its teaching package are developed and produced by a team of people in a dozen cities, from Alberta to Florida.) As work has changed, have our attitudes toward our work also changed? Has our satisfaction with work increased or decreased? Has the *psychological contract*—the sense of mutual obligations between workers and employers—become more or less trusting and secure? These are among the questions that fascinate **industrial-organizational (I/O) psychologists** as they apply psychology's principles to the workplace ([TABLE A.1](#)).

industrial-organizational (I/O) psychology the application of psychological concepts and methods to optimizing human behavior in workplaces.

TABLE A.1

I/O Psychology and Human Factors Psychology at Work

As scientists, consultants, and management professionals, industrial-organizational (I/O) psychologists may be found helping organizations to resolve work-family conflicts, build employee retention, address organizational climate, or promote team work. Human factors psychologists contribute to human safety and improved designs.

The modern workforce

The editorial team that supports the creation of this text and its resources works both in-house and from far-flung places. In column 1: Nancy Fleming in Massachusetts, Kathryn Brownson in Michigan, and Katie Pachnos in New York. In column 2: Lorie Hailey in Kentucky, Trish Morgan in Alberta, Carlise Stembridge in Minnesota, and Laura Burden in New York. In column 3: Danielle Stevens in Massachusetts, Betty Probert in Florida, and Christine Brune in Washington, DC.

Personnel Psychology

LOQ A-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

Psychologists assist organizations at various stages of selecting and assessing employees. They may help identify needed job skills, develop effective selection methods, recruit and evaluate appropriate applicants, introduce and

train new employees, and appraise their performance. They also help job seekers. Across four dozen studies, training programs (which teach job-search skills, improve self-presentation, boost self-confidence, promote goal setting, and enlist support) have nearly tripled job seekers' success (Liu et al., 2014).

Using Strengths for Successful Selection

As a new AT&T human resources executive, psychologist Mary Tenopyr (1997) was assigned to solve a problem: Customer-service representatives were failing at a high rate. After concluding that many of the hires were ill-matched to the demands of their new job, Tenopyr developed a new selection instrument:

She asked new applicants to respond to various test questions (without as yet making any use of their responses).

She followed up later to assess which of the applicants excelled on the job.

She identified the earlier test questions that best predicted success.

The happy result of her data-driven work was a new test that enabled AT&T to identify likely-to-succeed representatives. Personnel selection techniques such as this one aim to recruit people with the kind of strengths that will enable them and their organization to flourish. Marry the strengths of people with the tasks of organizations and the result is often prosperity and profit.

Do Interviews Predict Performance?

Employee selection usually includes an interview. And many interviewers feel confident of their ability to predict long-term job performance from a get-acquainted (*unstructured*) interview. What's therefore shocking is how error-prone interviewers' predictions may be when predicting job or graduate school success. From their review of 85 years of personnel-selection research, I/O psychologists Frank Schmidt and John Hunter (1998; Schmidt, 2002) determined that for all but less-skilled jobs, general mental ability best predicts on-the-job performance. Subjective overall evaluations from

informal interviews are more useful than handwriting analysis (which is worthless). But informal interviews are less informative than aptitude tests, work samples, job knowledge tests, and past job performance. After studying thousands of informal interviews and later job success, Google found “zero relationship. It’s a complete random mess” (Bock, 2013). *Structured interviews*, however, can produce more accurate predictions.

Unstructured Interviews and the Interviewer Illusion

Traditional, unstructured interviews can provide a sense of someone’s personality—their expressiveness, warmth, and verbal ability, for example. But these informal interviews also give interviewees considerable power to control the impression they are making in the interview situation (Barrick et al., 2009). Why, then, do many interviewers have such faith in their ability to discern interviewee’s fitness for a job? “I have excellent interviewing skills,” I/O consultants often hear, “so I don’t need reference checking as much as someone who doesn’t have my ability to read people.” Overrating one’s ability to predict people’s futures is called the *interviewer illusion* (Dana et al., 2013; Nisbett, 1987). Five factors explain interviewers’ overconfidence:

- *Interviewers presume that people are what they seem to be in the interview situation.* An unstructured interview may create a false impression of a person’s behavior toward others in different situations. Some interviewees may feign desired attitudes, others may be nervous. As personality psychologists explain, when meeting others, we discount the enormous influence of varying situations and mistakenly presume that what we see is what we will get. But research on everything from chattiness to conscientiousness reveals that how we behave reflects not only our enduring traits, but also the details of the particular situation (such as wanting to impress in a job interview).
- *Interviewers’ preconceptions and moods color how they perceive interviewees’ responses* (Cable & Gilovich, 1998; Macan & Dipboye, 1994). If interviewers instantly like a person who perhaps is similar to themselves, they may interpret the person’s assertiveness as indicating “confidence” rather than “arrogance.” If told certain applicants have been

prescreened, interviewers are disposed to judge them more favorably.

- *Interviewers judge people relative to those interviewed just before and after them* (Simonsohn & Gino, 2013). If you are being interviewed for business or medical school, hope for a time when the other interviewees have been weak.
- *Interviewers more often follow the successful careers of those they have hired than the successful careers of those they have rejected.* This missing feedback prevents interviewers from getting a reality check on their hiring ability.
- *Interviews disclose the interviewee's good intentions, which are less revealing than habitual behaviors* (Ouellette & Wood, 1998). Intentions matter. People can change. But the best predictor of the person we will be is the person we have been. Compared with work-avoiding university students, those who engage in their tasks are more likely, a decade and more later, to be engaged workers (Salmela-Aro et al., 2009). In one forty-year study, responsible, high-performing 12-year-old students tended to grow up to become successful, high-earning adult workers (Spengler et al., 2015). Wherever we go, we take ourselves along.

“Between the idea and reality . . . falls the shadow.”

T. S. Eliot, *The Hollow Men*, 1925

Hoping to improve prediction and selection, personnel psychologists have put people in simulated work situations, sought information on past performance, aggregated evaluations from multiple interviews, administered tests, and developed job-specific interviews.

Structured Interviews

Unlike casual conversation aimed at getting a feel for someone, [structured interviews](#) offer a disciplined method of collecting information. A personnel psychologist may analyze a job, script questions, and train interviewers. The interviewers then ask all applicants the same questions, in the same order, and rate each applicant on established scales.

structured interview an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales.

In an unstructured interview, someone might ask, “How organized are you?” “How well do you get along with people?” or “How do you handle stress?” Street-smart applicants know how to score high: “Although I sometimes drive myself too hard, I handle stress by prioritizing and delegating, and leaving time for sleep and exercise.”

By contrast, structured interviews pinpoint strengths (attitudes, behaviors, knowledge, and skills) that distinguish high performers in a particular line of work. The process includes outlining job-specific situations and asking candidates to explain how they would handle them, and how they handled similar situations in their prior employment. “Tell me about a time when you were caught between conflicting demands, without time to accomplish both. How did you handle that?” In its interviews, Google has asked, “Give me an example of a time when you solved an analytically difficult problem” (Bock, 2013).

To reduce memory distortions and bias, the interviewer takes notes and makes ratings as the interview proceeds and avoids irrelevant and follow-up questions. The structured interview therefore feels less warm, but that can be explained to the applicant: “This conversation won’t typify how we relate to each other in this organization.”

A review of 150 findings revealed that structured interviews had double the predictive accuracy of unstructured interviews (Schmidt & Hunter, 1998; Wiesner & Cronshaw, 1988). Structured interviews also reduce bias, such as against overweight applicants (Kutcher & Bragger, 2004).

If, instead, we let our intuitions bias the hiring process, noted Malcolm Gladwell (2000, [p. 86](#)), then “all we will have done is replace the old-boy network, where you hired your nephew, with the new-boy network, where you hire whoever impressed you most when you shook his hand. Social progress, unless we’re careful, can merely be the means by which we replace the obviously arbitrary with the not so obviously arbitrary.”

To recap, personnel psychologists help train job seekers, and they assist organizations in analyzing jobs, recruiting well-suited applicants, and selecting and placing employees. They also appraise employees’ performance

([FIGURE A.1](#))—our next topic.

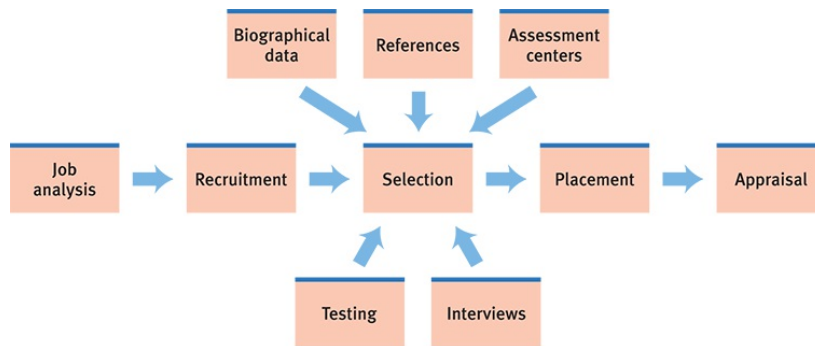

FIGURE A.1 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers

FIGURE A.1 Personnel psychologists at work

Personnel psychologists consult in human resources activities, from job definition to recruitment to employee appraisal.

Appraising Performance

Performance appraisal serves organizational purposes: It helps decide who to retain, how to appropriately reward and pay people, and how to better harness employee strengths, sometimes with job shifts or promotions. Performance appraisal also serves individual purposes: Feedback affirms workers' strengths and helps motivate needed improvements.

Performance appraisal methods include

- *checklists* on which supervisors simply check specific behaviors that describe the worker (“always attends to customers’ needs,” “takes long breaks”).
- *graphic rating scales* on which a supervisor checks, perhaps on a five-point scale, how often a worker is dependable, productive, and so forth.
- *behavior rating scales* on which a supervisor checks scaled behaviors that describe a worker’s performance. If rating the extent to which a worker “follows procedures,” the supervisor might mark the employee somewhere between “often takes shortcuts” and “always follows established procedures” (Levy, 2003).

In some organizations, performance feedback comes not only from supervisors but also from all organizational levels. If you join an organization

that practices *360-degree feedback* ([FIGURE A.2](#)), you will rate yourself, your manager, and your other colleagues, and you will be rated by your manager, other colleagues, and customers (Green, 2002). The net result is often more open communication and more complete appraisal.

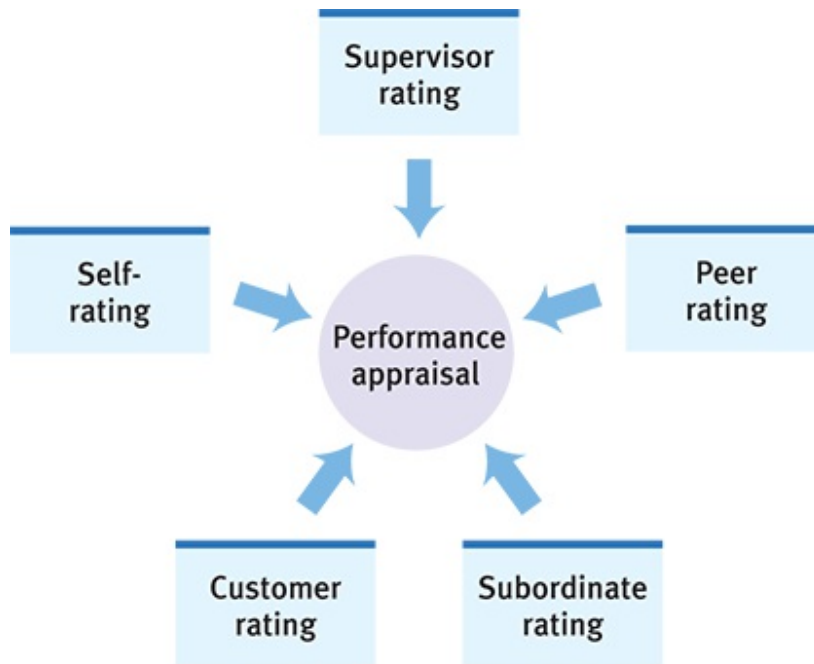

FIGURE A.2 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers

FIGURE A.2 360-degree feedback

With multisource 360-degree feedback, our knowledge, skills, and behaviors are rated by ourselves and surrounding others. Professors, for example, may be rated by their department chairs, their students, and their colleagues. After receiving all these ratings, professors discuss the 360-degree feedback with their department chair.

Performance appraisal, like other social judgments, is vulnerable to bias (Murphy & Cleveland, 1995). *Halo errors* occur when one's overall evaluation of an employee, or of a personal trait such as their friendliness, biases ratings of their specific work-related behaviors, such as their reliability. *Leniency* and *severity errors* reflect evaluators' tendencies to be either too easy or too harsh on everyone. *Recency errors* occur when raters focus only on easily remembered recent behavior. By using multiple raters and developing objective, job-relevant performance measures, personnel psychologists seek to support their organizations while also helping

employees perceive the appraisal process as fair.

RETRIEVAL PRACTICE

RP-2 A human resources director explains to you that “I don’t bother with tests or references. It’s all about the interview.” Based on I/O research, what concerns does this raise?

ANSWER: (1) Interviewers may presume people are what they seem to be in interviews. (2) Interviewers’ preconceptions and moods color how they perceive interviewees’ responses. (3) Interviewers judge people relative to other recent interviewees. (4) Interviewers tend to track the successful careers of those they hire, not the successful careers of those they reject. (5) Interviews tend to disclose prospective workers’ good intentions, not their habitual behaviors.

Organizational Psychology

LOQ A-4 What is the role of organizational psychologists?

Successfully recruiting, hiring, training, and appraising workers matters, but so does employee motivation and morale. Organizational psychologists assist with efforts to motivate and engage employees.

Satisfaction and Engagement at Work

I/O psychologists have found that satisfaction with work, and with work-life balance, feeds overall satisfaction with life (Bowling et al., 2010). Married men and women who have supportive spouses often enjoy a healthy balance between work and home life, with success in both arenas (Solomon & Jackson, 2014). Moreover, as health psychologists tell us, lower job stress, sometimes supported by telecommuting, feeds better health (Allen, T. D., et al., 2015).

“The only place success comes before work is in the dictionary.”

Former Green Bay Packers football coach Vince Lombardi

Courtesy of New Lanark Trust

Doing well while doing good

"The Great Experiment" At the end of the 1700s, the New Lanark, Scotland, cotton mill had more than 1000 workers. Many were children drawn from Glasgow's poorhouses. They worked 13-hour days and lived in grim conditions.

On a visit to Glasgow, Welsh-born Robert Owen—an idealistic young cotton-mill manager—chanced to meet and marry the mill owner's daughter. Owen and some partners purchased the mill and on the first day of the 1800s began what he said was "the most important experiment for the happiness of the human race that had yet been instituted at any time in any part of the world" (Owen, 1814). The exploitation of child and adult labor was, he observed, producing unhappy and inefficient workers. Owen showed *transformational leadership* when he undertook numerous innovations: a nursery for preschool children, education for older children (with encouragement

rather than corporal punishment), Sundays off, health care, paid sick days, unemployment pay for days when the mill could not operate, and a company store selling goods at reduced prices.

He also innovated a goals- and worker-assessment program that included detailed records of daily productivity and costs but with “no beating, no abusive language.”

The ensuing commercial success fueled a humanitarian reform movement. By 1816, with decades of profitability still ahead, Owen believed he had demonstrated “that society may be formed so as to exist without crime, without poverty, with health greatly improved, with little if any misery, and with intelligence and happiness increased a hundredfold.” Although his Utopian vision has not been fulfilled, Owen’s great experiment laid the groundwork for employment practices that have today become accepted in much of the world.

Satisfied employees also contribute to successful organizations. Positive moods at work enhance creativity, persistence, and helpfulness (Ford et al., 2011; Jeffrey et al., 2014; Shockley et al., 2012). Are engaged, happy workers also less often absent? Less likely to quit? Less prone to theft? More punctual? More productive? Statistical digests of prior research have found a modest positive correlation between individual job satisfaction and performance (Judge et al., 2001; Ng, T. W. H., et al., 2009; Parker et al., 2003). In one analysis of 4500 employees at 42 British manufacturing companies, the most productive workers were those who found their work environment satisfying (Patterson et al., 2004).

Some organizations seem to have a knack for cultivating more engaged and productive employees. In the United States, *Fortune*’s “100 Best Companies to Work For” have also produced markedly higher-than-average returns for their investors (Fulmer et al., 2003). And consider a study of more than 198,000 employees in nearly 8000 business units of 36 large companies (including some 1100 bank branches, 1200 stores, and 4200 teams or departments). James Harter, Frank Schmidt, and Theodore Hayes (2002) explored correlations between various measures of organizational success and *employee engagement*—the extent of workers’ involvement, enthusiasm, and identification with their organizations ([TABLE A.2](#)). They found that engaged workers (compared with disengaged workers who are just putting in their time) knew what was expected of them, had what they needed to do their work, felt fulfilled in their work, had regular opportunities to do what

they do best, perceived that they were part of something significant, and had opportunities to learn and develop. They also found that business units with engaged employees had more loyal customers, lower turnover rates, higher productivity, and greater profits.

TABLE A.2
Three Types of Employees

Engaged: working with passion and feeling a profound connection to their company or organization.
Not engaged: putting in the time but investing little passion or energy in their work.
Actively disengaged: unhappy workers undermining what their colleagues accomplish.

Information from Gallup via Crabtree, 2005.

MLive/Advance/Barcroft Media

An engaged employee

Mohamed Mamow, left, was joined by his employer in saying the Pledge of Allegiance as he became a U.S. citizen. Mamow and his wife met in a Somali refugee camp and have five children, whom he has supported

by working as a machine operator. Mindful of his responsibility—"I don't like to lose my job. I have a responsibility for my children and my family"—he would arrive for work a half hour early and tend to every detail on his shift. "He is an extremely hard-working employee," noted his employer, and "a reminder to all of us that we are really blessed" (Roelofs, 2010).

But what causal arrows explain this correlation between business success and employee morale and engagement? Does success boost morale, or does high morale boost success? In a follow-up longitudinal study of 142,000 workers, researchers found that, over time, employee attitudes predicted future business success (more than the other way around) (Harter et al., 2010). Many other studies confirm that happy workers tend to be good workers (Ford et al., 2011; Seibert et al., 2011; Shockley et al., 2012). One analysis compared companies with top-quartile versus below-average employee engagement levels. Over a three-year period, earnings grew 2.6 times faster for the companies with highly engaged workers (Ott, 2007). It pays to have employees engaged.

Effective Leadership

LOQ A-5 How can leaders be most effective?

Great managers support employees' well-being, articulate goals clearly, and lead in ways that suit the situation and consider the cultural context.

Setting Specific, Challenging Goals

Measurable objectives, such as "finish gathering the history paper information by Friday," focus our attention and stimulate us to persist and to be creative. Goals motivate achievement, especially when combined with progress reports (Harkin et al., 2016). For many people, a landmark in time—a special birthday, the new year or new school term, graduation, a new job—spurs personal goal setting (Dai et al., 2014). Action plans that break large goals into smaller steps (subgoals) and that specify "implementation intentions"—when, where, and how to achieve those steps—increase the chances of completing a project on time (Fishbach et al., 2006; Gollwitzer &

Sheeran, 2006). Through a task's ups and downs, we best sustain our mood and motivation when we focus on immediate goals (such as daily study) rather than distant goals (such as a course grade). Better to have our nose to the grindstone than our eye on the ultimate prize (Houser-Marko & Sheldon, 2008).

Thus, before beginning each new edition of this book, our author-editor-staff team *manages by objectives*—we agree on target dates for the completion and editing of each draft. If we focus on achieving each of these short-term goals, the prize—an on-time book—takes care of itself. So, to motivate high productivity, effective leaders work with people to define explicit goals, subgoals, and implementation plans, and then provide feedback on progress.

Choosing an Appropriate Leadership Style

Effective leaders of laboratory groups, work teams, and large corporations often exude *charisma* (Goethals & Allison, 2014; House & Singh, 1987; Shamir et al., 1993). People with charisma have the ability to motivate people to cooperate toward a common goal (Grabo & van Vugt, 2016).

“Good leaders don’t ask more than their constituents can give, but they often ask—and get—more than their constituents intended to give or thought it was possible to give.”

John W. Gardner, *Excellence*, 1984

Although charismatic leaders can inspire, **leadership**—the ability to motivate and influence people to enable their group’s success—varies, depending both on the leader and the situation. In some situations (think of a commander leading troops into battle), a *directive* style may be needed (Fiedler, 1981). In other situations—developing a comedy show, for example—a leader might get better results using a *democratic* style that welcomes team member creativity.

leadership an individual’s ability to motivate and influence others to contribute to their group’s success.

Leaders differ in the personal qualities they bring to the job. Some excel at **task leadership**—by setting standards, organizing work, and focusing attention on goals. To keep the group centered on its mission, task leaders typically use a directive style, which can work well if the leader gives good directions (Fiedler, 1987).

task leadership goal-oriented leadership that sets standards, organizes work, and focuses attention on goals.

Other managers excel at **social leadership**. They explain decisions, help group members solve their conflicts, and build teams that work well together (Evans & Dion, 1991; Pfaff et al., 2013). Social leaders, many of whom are women, often have a democratic style. They share authority and welcome team members' opinions. Social leadership and team-building increases morale and productivity (Shuffler et al., 2011, 2013). We usually feel more satisfied and motivated, and perform better, when we can participate in decision making (Cawley et al., 1998; Pereira & Osburn, 2007). Moreover, when members are sensitive to one another and participate equally, groups solve problems with greater “collective intelligence” (Woolley et al., 2010).

social leadership group-oriented leadership that builds teamwork, mediates conflict, and offers support.

In one study of 50 Dutch companies, the firms with the highest morale had chief executives who most inspired their colleagues “to transcend their own self-interests for the sake of the collective” (de Hoogh et al., 2004).

Transformational leadership of this kind motivates others to identify with and commit themselves to the group's mission. Transformational leaders, many of whom are natural extraverts, articulate high standards, inspire people to share their vision, and offer personal attention (Bono & Judge, 2004). The frequent result is more engaged, trusting, and effective workers (Turner et al., 2002). Women more than men tend to exhibit transformational leadership

qualities. Alice Eagly (2007, 2013) believes this helps explain why companies with female top managers have tended to enjoy superior financial results, even after controlling for such variables as company size.

Studies in India, Taiwan, and Iran suggest that effective managers—whether in coal mines, banks, or government offices—often exhibit a high degree of *both* task and social leadership (Smith & Tayeb, 1989). As achievement-minded people, effective managers care about how well work is done, yet they are sensitive to their subordinates' needs. Workers in family-friendly organizations that offer flexible-time hours report feeling greater job satisfaction and loyalty to their employers (Butts et al., 2013; Roehling et al., 2001). Over time, U.S. senators who practice common virtues (humility, wisdom, courage) become more influential in leadership roles than do those who practice manipulation and intimidation (ten Brinke et al., 2016). Social virtues work.

POSITIVE REINFORCEMENT Effective leadership often builds on a basic principle of *operant conditioning*: To teach a behavior, catch a person doing something right and reinforce it. It sounds simple, but many managers are like parents who, when a child brings home a near-perfect school report card, focus on the one low grade in a troublesome biology class and ignore the rest. “Sixty-five percent of Americans received NO praise or recognition in the workplace last year,” reported the Gallup Organization (2004).

Scott Eklund/AP Images

The power of positive coaching

Football coach Pete Carroll, who led the University of Southern California to two national championships and the Seattle Seahawks to a Super Bowl championship, has combined positive enthusiasm and fun workouts with “a commitment to a nurturing environment that allows people to be themselves while still being accountable to the team” (Trotter, 2014). “It shows you can win with positivity,” noted Seahawks star defensive player Richard Sherman. “It’s literally all positive reinforcement,” said teammate Jimmy Graham (Belson, 2015).

FULFILLING THE NEED TO BELONG A work environment that satisfies employees’ need to belong is energizing. Employees who enjoy high-quality colleague relationships engage their work with more vigor (Carmeli et al., 2009). Gallup researchers have asked more than 15 million employees worldwide if they have a “best friend at work.” The 30 percent who do “are *seven times* as likely to be engaged in their jobs” as those who don’t, report Tom Rath and James Harter (2010). And, as we noted earlier, positive, engaged employees are a mark of thriving organizations.

The New Yorker Collection, 1988, Anthony Taber from cartoonbank.com. All Rights Reserved.

PARTICIPATIVE MANAGEMENT Employee participation in decision making is common in Sweden, Japan, the United States, and elsewhere (Cawley et al., 1998; Sundstrom et al., 1990). Workers given a chance to voice their opinion and be part of the decision-making process have responded more positively to the final decision (van den Bos & Spruijt, 2002). They also feel more empowered, and are likely, therefore, to be more creative and committed (Hennessey & Amabile, 2010; Seibert et al., 2011).

The ultimate in employee participation is the employee-owned company.

One such company in my [DM's] town is the Fleetwood Group—a thriving 165-employee manufacturer of educational furniture and wireless electronic clickers. Every employee owns part of the company, and as a group they own 100 percent. The more years employees work, the more they own, yet no one owns more than 5 percent. Like every corporate president, Fleetwood's president works for his stockholders—who also just happen to be his employees.

As a company that endorses faith-inspired *servant leadership* and “respect and care for each team member-owner,” Fleetwood is free to place people above profits. Thus, when orders lagged during a recession, the employee-owners decided that job security meant more to them than profits. So the company paid otherwise idle workers to do community service, such as answering phones at nonprofit agencies and building Habitat for Humanity houses. Employee ownership attracts and retains talented people, which for Fleetwood has meant company success.

Cultural Influences on Leadership Styles

LOQ A-6 What cultural influences need to be considered when choosing an effective leadership style?

Industrial-organizational psychology sprang from North American roots. So, how well do its leadership principles apply to global cultures?

Investigators worldwide have undertaken Project GLOBE (Global Leadership and Organizational Behavior Effectiveness), to study cultural variations in leadership expectations (House et al., 2001). Some cultures, for example, encourage collective sharing of resources and rewards; others are more individualist. Some cultures minimize and others accentuate gender roles. Some cultures prioritize being friendly, caring, and kind, and others encourage aggressiveness. The program's first research phase studied 17,300 leaders of 950 organizations in 61 countries (Brodbeck et al., 2008; Dorfman et al., 2012). One finding: Leaders who fulfill expectations, such as by being directive in some cultures or participative in others, tend to be successful. Cultures shape leadership and what makes for leadership success.

Nevertheless, some leader behaviors are universally effective. From its massive study of nearly 50,000 business units in 45 countries, the Gallup

Organization observed that thriving companies tend to focus on identifying and enhancing employee *strengths* (rather than punishing their deficiencies). Doing so predicts increased employee engagement, customer satisfaction, and profitability (Rigoni & Asplund, 2016a,b). “Strengths-based” leadership pays dividends. By caring about their employees and engaging and affirming their strengths, such leaders support happier, more creative, more productive workers with less absenteeism and turnover (Amabile & Kramer, 2011; De Neve et al., 2013). Moreover, the same principles affect student satisfaction, retention, and future success (Larkin et al., 2013; Ray & Kafka, 2014). Students who feel supported by caring friends and mentors, and engaged in their campus life, tend to persist and ultimately succeed during school and after graduation.

RETRIEVAL PRACTICE

RP-3 What characteristics are important for *transformational leaders*?

ANSWER: *Transformational leaders* are able to inspire others to share a vision and commit themselves to a group’s mission. They tend to be naturally extraverted and set high standards.

* * *

We have considered *personnel psychology* (the I/O subfield that focuses on training job seekers, and assisting with employee selection, placement, appraisal, and development). And we have considered *organizational psychology* (the I/O subfield that focuses on worker satisfaction and productivity, and on organizational change). Finally, we turn to *human factors psychology*, which explores the human-machine interface.

Human Factors Psychology

LOQ A-7 How do human factors psychologists work to create user-friendly machines and work settings?

Designs sometimes neglect the human factor. Cognitive scientist Donald

Norman (2001) bemoaned the complexity of assembling his new HDTV, related components, and seven remotes into a usable home theater system: “I was VP of Advanced Technology at Apple. I can program dozens of computers in dozens of languages. I understand television, really, I do. . . . It doesn’t matter: I am overwhelmed.”

Human factors psychologists work with designers and engineers to tailor appliances, machines, and work settings to our natural perceptions and inclinations. Bank ATM machines are internally more complex than remote controls ever were, yet thanks to human factors engineering, ATMs are easier to operate. Digital recorders have solved the TV recording problem with a simple select-and-click menu system (“record that one”). Apple similarly engineered easy usability with the iPhone and iPad. Handheld and wearable technologies are increasingly making use of *haptic* (touch-based) feedback—opening a phone with a thumbprint, sharing your heartbeat via a smartwatch, or having GPS directional instructions (“turn left” arrow) “drawn” on your skin with other wrist-worn devices.

Norman hosts a website (jnd.org) that illustrates good designs that fit people (**FIGURE A.3**). Human factors psychologists also help design efficient environments. An ideal kitchen layout, researchers have found, puts needed items close to their usage point and near eye level. It locates work areas to enable doing tasks in order, such as placing the refrigerator, stove, and sink in a triangle. It creates counters that enable hands to work at or slightly below elbow height (Boehm-Davis, 2005).

FIGURE A.3 Myers/DeWall, *Psychology*, 12e, © 2018 Worth Publishers
Ride On Carry On; OXO Good Grips

FIGURE A.3 Designing products that fit people

Human factors expert Donald Norman offers these and other examples of effectively designed products. The Ride On Carry On foldable chair attachment, “designed by a flight attendant mom,” enables a small suitcase to double as a stroller. The OXO measuring cup allows the user to see the quantity from above.

Understanding human factors can help prevent accidents. By studying the human factor in driving accidents, psychologists seek to devise ways to reduce the distractions, fatigue, and inattention that contribute to 1.25 million annual worldwide traffic fatalities (WHO, 2016a). At least two-thirds of commercial air accidents have been caused by human error (Shappell et al., 2007). After beginning commercial flights in the 1960s, the Boeing 727 was involved in several landing accidents caused by pilot error. Psychologist Conrad Kraft (1978) noted a common setting for these accidents: All took place at night, and all involved landing short of the runway after crossing a dark stretch of water or unilluminated ground. Kraft reasoned that, on rising terrain, city lights beyond the runway would project a larger retinal image, making the ground seem farther away than it was. By re-creating these conditions in flight simulations, Kraft discovered that pilots were deceived into thinking they were flying higher than their actual altitudes ([FIGURE A.4](#)). Aided by Kraft’s finding, the airlines began requiring the co-pilot to monitor the altimeter—calling out altitudes during the descent—and the accidents diminished.

FIGURE A.4 Myers/DeWall, *Psychology*, 12e,
© 2018 Worth Publishers
Data from Kraft, 1978.

FIGURE A.4 The human factor in accidents

Lacking distance cues when approaching a runway from over a dark surface, pilots simulating a night landing tended to fly too low.

Human factors psychologists can also help us to function in other settings. Consider the available *assistive listening* technologies in various theaters, auditoriums, and places of worship. One technology, commonly available in the United States, requires a headset attached to a pocket-sized receiver. The well-meaning people who provide these systems correctly understand that the technology puts sound directly into the user's ears. Alas, few people with hearing loss elect the hassle and embarrassment of locating, requesting, wearing, and returning a conspicuous headset. Most such units therefore sit in closets. Britain, the Scandinavian countries, Australia, and now many parts of the United States have instead installed *loop systems* (see hearingloop.org) that broadcast customized sound directly through a person's own hearing aid. When suitably equipped, a hearing aid can be transformed by a discreet touch of a switch into a customized in-the-ear speaker. When offered convenient, inconspicuous, personalized sound, many more people elect to use assistive listening.

The better you know something, the less you remember about how hard it was to learn.

Psychologist Steven Pinker, *The Sense of Style*, 2014

Designs that enable safe, easy, and effective interactions between people and technology often seem obvious after the fact. Why, then, aren't they more common? Technology developers, like all of us, sometimes mistakenly assume that others share their expertise—that what's clear to them will similarly be clear to others (Camerer et al., 1989; Nickerson, 1999). When people rap their knuckles on a table to convey a familiar tune (try this with a friend), they often expect their listener to recognize it. But for the listener, this is a near-impossible task (Newton, 1991). When you know a thing, it's hard to mentally simulate what it's like not to know, and that is called the *curse of knowledge*.

The point to remember: Everyone benefits when designers and engineers tailor machines, technologies, and environments to fit human abilities and behaviors, when they user-test their work before production and distribution, and when they remain mindful of the curse of knowledge.

RETRIEVAL PRACTICE

RP-4 What is the *curse of knowledge*, and what does it have to do with the work of human factors psychologists?

ANSWER: To develop safer machines and work environments, human factors psychologists stay mindful of the curse of knowledge—the tendency for experts to mistakenly assume that others share their knowledge.

Steven Day/AP Images

The human factor in safe landings

Advanced cockpit design and rehearsed emergency procedures aided pilot Chesley “Sully” Sullenberger, a U.S. Air Force Academy graduate who earned a Master’s degree in industrial psychology. In 2009, Sullenberger’s instantaneous decisions safely guided his disabled airplane onto New York City’s Hudson River, where all 155 of the passengers and crew were safely evacuated.

REVIEW Psychology at Work

LEARNING OBJECTIVES

Test yourself by taking a moment to answer each of these Learning Objective Questions (repeated here from within this section). Then check your answer—a click away in the e-book, and in [Appendix C](#) of the printed text. Research suggests that trying to answer these questions on your own will improve your long-term retention (McDaniel et al., 2009, 2015).

LOQ A-1 What is *flow*?

LOQ A-2 What are three key areas of study related to industrial-organizational psychology?

LOQ A-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

LOQ A-4 What is the role of organizational psychologists?

LOQ A-5 How can leaders be most effective?

LOQ A-6 What cultural influences need to be considered when choosing an effective leadership style?

LOQ A-7 How do human factors psychologists work to create user-friendly machines and work settings?

MASTER THE MATERIAL

Test yourself repeatedly throughout your studies. This will not only help you figure out what you know and don't know; the testing itself will help you learn and remember the information more effectively thanks to the *testing effect*.

People who view their work as a calling often experience _____, a focused state of consciousness, with diminished awareness of themselves and of time.

_____ psychologists assist with job seeking, and the recruitment, selection, placement, training, appraisal, and development of employees;

_____ psychologists focus on how people and machines interact, and on optimizing devices and work environments.

A personnel psychologist scripted a set of questions to ask all applicants for a job opening. She then trained the firm's interviewers to ask only those questions, to take notes, and to rate applicants' responses. This technique is known as a(n)

- a. structured interview.
- b. unstructured interview.
- c. performance appraisal checklist.
- d. behavior rating scale.

In your job, you rate your own performance, your manager's, and your peers'. Your manager, your peers, and your customers also rate your performance. Your organization is using a form of performance appraisal called

- a. flow procedure.
- b. graphic feedback.
- c. structured interviews.
- d. 360-degree feedback.

What type of goals will best help you stay focused and motivated to do your finest work in this class?

Research indicates that women are often social leaders. They are also more likely than men to have a _____ leadership style.

Effective managers often exhibit

- a. only task leadership.
- b. only social leadership.
- c. both task and social leadership, depending on the situation and the person.
- d. task leadership for building teams and social leadership for setting standards.

Human factors psychologists focus primarily on

- a. training and developing employees.
- b. appraising employee performance.
- c. maximizing worker satisfaction.
- d. improving the design of machines and environments.

Answers are a click away in the e-book, and in [Appendix D](#) at the back of the printed text.

Use  **LearningCurve** to create your personalized study plan, which will direct you to the Macmillan resources that will help you most.

APPENDIX B Career Fields in Psychology

Jennifer Zwolinski
University of San Diego

What can you do with a degree in psychology? Lots!

As a psychology major, you will graduate with a scientific mindset and an awareness of basic principles of human behavior (biological mechanisms, nature–nurture interactions, life-span development, cognition, psychological disorders, social interaction). This background will prepare you for success in many areas, including business, the helping professions, health services, marketing, law, sales, and teaching. You may even go on to graduate school for specialized training to become a psychology professional. This appendix provides an overview of some of psychology’s key career fields.¹ For more detailed information, see *Pursuing a Psychology Career* in LaunchPad (LaunchPadWorks.com), where you can learn more about the many interesting options available to those with bachelor’s, master’s, and doctoral degrees in psychology.

If you are like most psychology students, you may be unaware of the wide variety of specialties and work settings available in psychology (Terre & Stoddart, 2000). To date, the American Psychological Association (APA) has 54 divisions (apa.org/about/division/index.aspx) that represent the popular subfields and interest groups of APA members (**TABLE B.1**). For example, Division 2 (Society for the Teaching of Psychology) offers an excellent career exploration resource for those interested in learning about the hundreds of career options available for students with an undergraduate degree in psychology (teachpsych.org/psycareer).

TABLE B.1**APA Divisions by Number and Name**

1. Society for General Psychology	29. Society for the Advancement of Psychotherapy
2. Society for the Teaching of Psychology	30. Society of Psychological Hypnosis
3. Society for Experimental Psychology and Cognitive Science	31. State, Provincial, and Territorial Psychological Association Affairs
4. <i>There is no active Division 4.</i>	32. Society for Humanistic Psychology
5. Quantitative and Qualitative Methods	33. Intellectual and Developmental Disabilities/Autism Spectrum Disorders
6. Society for Behavioral Neuroscience and Comparative Psychology	34. Society for Environmental, Population, and Conservation Psychology
7. Developmental Psychology	35. Society for the Psychology of Women
8. Society for Personality and Social Psychology	36. Society for the Psychology of Religion and Spirituality
9. Society for the Psychological Study of Social Issues (SPSSI)	37. Society for Child and Family Policy and Practice
10. Society for the Psychology of Aesthetics, Creativity, and the Arts	38. Society for Health Psychology

The following paragraphs (arranged alphabetically) describe some of psychology's main career fields, most of which require a graduate degree.

CLINICAL PSYCHOLOGISTS promote psychological health in individuals, groups, and organizations. Some clinical psychologists specialize in specific psychological disorders. Others treat a range of disorders, from adjustment difficulties to severe psychopathology. Clinical psychologists often provide therapy but may also engage in research, teaching, assessment, and consultation. Clinical psychologists work in a variety of settings, including private practice, mental health service organizations, schools, universities, industries, legal systems, medical systems, counseling centers, government agencies, correctional facilities, nonprofit organizations, and military services.

To become a clinical psychologist, you will need to earn a doctorate from a clinical psychology program. The APA sets the standards for clinical psychology graduate programs, offering *accreditation* (official recognition) to those who meet their standards. In all U.S. states, clinical psychologists working in independent practice must obtain a license to offer services such as therapy and testing.

COGNITIVE PSYCHOLOGISTS study thought processes and focus on such topics as perception, language, attention, problem solving, memory, judgment and decision making, and intelligence. Research interests include designing computer-based models of thought processes and identifying biological correlates of cognition. As a cognitive psychologist, you might work as a professor, industrial consultant, or human factors specialist in an educational or business setting.

COMMUNITY PSYCHOLOGISTS move beyond focusing on specific individuals or families and deal with broad problems of mental health in community settings. These psychologists believe that human behavior is powerfully influenced by the interaction between people and their physical,

social, political, and economic environments. They seek to promote psychological health by enhancing environmental settings—focusing on preventive measures and crisis intervention, with special attention to the problems of underserved groups and minority groups. Some community psychologists collaborate with professionals in other areas, such as public health, with a shared emphasis on prevention. As a community psychologist, your work settings could include federal, state, and local departments of mental health, corrections, and welfare. You might conduct research or help evaluate research in health service settings, serve as an independent consultant for a private or government agency, or teach and consult as a college or university faculty member.

Karen Moskowitz/The Image Bank/Getty Images

Cognitive consulting

Cognitive psychologists may advise businesses on how to operate more effectively by understanding the human factors involved.

COUNSELING PSYCHOLOGISTS help people adjust to life transitions or make lifestyle changes. Although similar to clinical psychologists, counseling psychologists typically help people with adjustment problems rather than severe psychopathology. Like clinical psychologists, counseling psychologists conduct therapy and provide assessments to individuals and groups. As a counseling psychologist, you would likely emphasize your clients' strengths, helping them to use their own skills, interests, and abilities to cope during transitions. You might find yourself working in an academic

setting as a faculty member or administrator or in a university counseling center, community mental health center, business, or private practice. As with clinical psychology, if you plan to work in independent practice you will need to obtain a state license to provide counseling services to the public.

DEVELOPMENTAL PSYCHOLOGISTS conduct research on age-related behavioral changes and apply their scientific knowledge to educational, child-care, policy, and related settings. As a developmental psychologist, you would investigate change across a broad range of topics, including the biological, psychological, cognitive, and social aspects of development. Developmental psychology informs a number of applied fields, including educational psychology, school psychology, child psychopathology, and gerontology. The field also informs public policy in areas such as education and child-care reform, maternal and child health, and attachment and adoption. You would probably specialize in a specific stage of the life span, such as infancy, childhood, adolescence, or middle or late adulthood. Your work setting could be an educational institution, day-care center, youth group program, or senior center.

AP Photo

Community care

Community psychologists in Haiti have helped residents work through the ongoing emotional challenges that followed the devastating 2010 earthquake and, more recently, the widely destructive 2016 hurricane.

EDUCATIONAL PSYCHOLOGISTS are interested in the psychological

processes involved in learning. They study the relationship between learning and the physical and social environments, and they develop strategies for enhancing the learning process. As an educational psychologist, working in a university psychology department or school of education, you might conduct basic research on topics related to learning, or develop innovative methods of teaching to enhance the learning process. You might design effective tests, including measures of aptitude and achievement. You might be employed by a school or government agency or charged with designing and implementing effective employee-training programs in a business setting.

ENVIRONMENTAL PSYCHOLOGISTS study the interaction of individuals with their natural and built (urban) environments. They are interested in how we influence and are affected by these environments. As an environmental psychologist, you might study wildlife conservation, the impact of urbanization on health, or cognitive factors involved in sustainable lifestyle choices. Environmental psychologists tend to address these kinds of questions by working with other professionals as part of an interdisciplinary team. As an environmental psychologist, you might work in a consulting firm, an academic setting, the nonprofit sector, or the government.

EXPERIMENTAL PSYCHOLOGISTS are a diverse group of scientists who investigate a variety of basic behavioral processes in humans and other animals. Prominent areas of experimental research include comparative methods of science, motivation, learning, thought, attention, memory, perception, and language. Most experimental psychologists identify with a particular subfield, such as cognitive psychology, depending on their interests and training. Experimental research methods are not limited to the field of experimental psychology; many other subfields rely on experimental methodology to conduct studies. As an experimental psychologist, you would most likely work in an academic setting, teaching courses and supervising students' research in addition to conducting your own research. Or you might be employed by a research institution, zoo, business, or government agency.

FORENSIC PSYCHOLOGISTS apply psychological principles to legal issues. They conduct research on the interface of law and psychology, help to create public policies related to mental health, help law-enforcement agencies in criminal investigations, or consult on jury selection and deliberation processes. They also provide assessment to assist the legal community.

Although most forensic psychologists are clinical psychologists, many have expertise in other areas of psychology, such as social or cognitive psychology. Some also hold law degrees. As a forensic psychologist, you might work in a university psychology department, law school, research organization, community mental health agency, law-enforcement agency, court, or correctional setting.

Criminal investigation

Forensic psychologists may be called on to assist police officers investigating a crime scene, as seen here after a shooting in Florida. Most forensic work, however, occurs in the lab and for the judicial system.

HEALTH PSYCHOLOGISTS are researchers and practitioners concerned with psychology's contribution to promoting health and preventing disease. As applied psychologists or clinicians, they may help individuals lead healthier lives by designing, conducting, and evaluating programs to stop smoking, lose weight, improve sleep, manage pain, prevent the spread of sexually transmitted infections, or treat psychosocial problems associated with chronic and terminal illnesses. As researchers and clinicians, they identify conditions and practices associated with health and illness to help create effective interventions. In public service, health psychologists study

and work to improve government policies and health care systems. As a health psychologist, you could be employed in a hospital, medical school, rehabilitation center, public health agency, college or university, or, if you are also a clinical psychologist, in private practice.

INDUSTRIAL-ORGANIZATIONAL (I/O) PSYCHOLOGISTS study the relationship between people and their working environments. They may develop new ways to increase productivity, improve personnel selection, or promote job satisfaction in an organizational setting. Their interests include organizational structure and change, consumer behavior, and personnel selection and training. As an I/O psychologist, you might conduct workplace training or provide organizational analysis and development. You may find yourself working in business, industry, the government, or a college or university. Or you may be self-employed as a consultant or work for a management consulting firm. (For more on I/O psychology, see [Appendix A](#), “Psychology at Work.”)

NEUROPSYCHOLOGISTS investigate the relationship between neurological processes (structure and function of the brain) and behavior. As a neuropsychologist you might assess, diagnose, or treat central nervous system disorders, such as Alzheimer’s disease or stroke. You might also evaluate individuals for evidence of head injuries; learning and developmental disabilities, such as autism spectrum disorder; and other psychiatric disorders, such as attention-deficit/hyperactivity disorder (ADHD). If you are a *clinical neuropsychologist*, you might work in a hospital’s neurology, neurosurgery, or psychiatric unit. Neuropsychologists also work in academic settings, where they conduct research and teach.

Assessing and supporting children

School psychologists may find themselves working with children individually or in groups. They receive interdisciplinary training in mental health assessment and behavior analysis, research methods and design, and special needs education. They work primarily in schools, but also in a range of other settings, including pediatric hospitals, mental health centers, and correctional facilities.

PSYCHOMETRIC AND QUANTITATIVE PSYCHOLOGISTS study the methods and techniques used to acquire psychological knowledge. A psychometric psychologist may update existing neurocognitive or personality tests or devise new tests for use in clinical and school settings or in business and industry. These psychologists also administer, score, and interpret such tests. Quantitative psychologists collaborate with researchers to design, analyze, and interpret the results of research programs. As a psychometric or quantitative psychologist, you will need to be well trained in research methods, statistics, and computer technology. You will most likely be employed by a university or college, a testing company, a private research firm, or a government agency.

REHABILITATION PSYCHOLOGISTS are researchers and practitioners who work with people who have lost optimal functioning after an accident,

illness, or other event. As a rehabilitation psychologist, you would probably work in a medical rehabilitation institution or hospital. You might also work in a medical school, university, state or federal vocational rehabilitation agency, or in private practice serving people with physical disabilities.

SCHOOL PSYCHOLOGISTS are involved in the assessment of and intervention for children in educational settings. They diagnose and treat cognitive, social, and emotional problems that may negatively influence children's learning or overall functioning at school. As a school psychologist, you would collaborate with teachers, parents, and administrators, making recommendations to improve student learning. You would work in an academic setting, a federal or state government agency, a child guidance center, or a behavioral research laboratory.

SOCIAL PSYCHOLOGISTS are interested in our interactions with others. Social psychologists study how our beliefs, feelings, and behaviors are affected by and influence other people. They study topics such as attitudes, aggression, prejudice, interpersonal attraction, group behavior, and leadership. As a social psychologist, you would probably be a college or university faculty member. You might also work in organizational consultation, market research, or other applied psychology fields, including social neuroscience. Some social psychologists work for hospitals, federal agencies, social networking sites, or businesses performing applied research.

SPORT PSYCHOLOGISTS study the psychological factors that influence, and are influenced by, participation in sports and other physical activities. Their professional activities include coach education and athlete preparation, as well as research and teaching. Sport psychologists who also have a clinical or counseling degree can apply those skills to working with individuals with psychological problems, such as anxiety or substance abuse, that might interfere with optimal performance. As a sport psychologist, if you were not working in an academic or research setting, you would most likely work as part of a team or an organization or in a private capacity.

Cricket cures

Sport psychologists often work directly with athletes to help them improve their performance. Here a sport psychologist consults with Brendon McCullum, a record-breaking athlete who plays international cricket for New Zealand.

So, the next time someone asks you what you will do with your psychology degree, tell them you have a lot of options. You might use your acquired skills and understanding to get a job and succeed in any number of fields, or you might pursue graduate school and then career opportunities in associated professions. In any case, what you have learned about behavior and mental processes will surely enrich your life (Hammer, 2003).

APPENDIX C Complete Chapter Reviews

PROLOGUE

THE STORY OF PSYCHOLOGY

What Is Psychology?

P-1 How is psychology a science, and why is it the “rat is always right”?

Psychology’s findings, based on an *empirical approach*, are the result of careful observation and testing. Sifting sense from nonsense requires a scientific attitude. The so-called “rat” (as in a psychologist’s maze, for example) is always right because the facts are the facts, even when we find them surprising.

P-2 What are the three key elements of the scientific attitude, and how do they support scientific inquiry?

The scientific attitude equips us to be curious, skeptical, and humble in scrutinizing competing ideas or our own observations. Curiosity triggers new ideas, skepticism encourages attention to the facts, and humility helps us discard predictions that can’t be verified by research. Together, these three key elements make modern science possible.

P-3 How does critical thinking feed a scientific attitude, and smarter thinking for everyday life?

Critical thinking puts ideas to the test by examining assumptions, appraising the source, discerning hidden biases, evaluating evidence, and assessing conclusions.

P-4 What were some important milestones in psychology’s early development?

Wilhelm Wundt established the first psychological laboratory in 1879 in Germany. Two early schools of thought in psychology were *structuralism* and *functionalism*.

P-5 How did behaviorism, Freudian psychology, and humanistic

psychology further the development of psychological science?

Early researchers defined *psychology* as “the science of mental life.” In the 1920s, under the influence of John B. Watson and the behaviorists, the field’s focus changed to the “scientific study of observable behavior.” *Behaviorism* became one of psychology’s two major forces well into the 1960s. However, the second major force of Freudian psychology, along with the influence of *humanistic psychology*, revived interest in the study of mental processes.

P-6 How has contemporary psychology focused on cognition, on biology and experience, on culture and gender, and on human flourishing?

The *cognitive* revolution in the 1960s led psychology back to its early interest in the mind, and to its current definition as the science of behavior and mental processes. Our growing understanding of biology and experience has fed psychology’s most enduring debate. The *nature–nurture issue* centers on the relative contributions of genes and experience, and their interaction in specific environments. Charles Darwin’s view that *natural selection* shapes behaviors as well as bodies led to *evolutionary psychology*’s study of our similarities because of our common biology and evolutionary history, and *behavior genetics*’ focus on the relative power and limits of genetic and environmental influences on behavior. Cross-cultural and gender studies have diversified psychology’s assumptions while also reminding us of our similarities. Attitudes and behaviors may vary somewhat by gender or across *cultures*, but because of our shared human kinship, the underlying processes and principles are more similar than different. Psychology’s traditional focus on understanding and treating troubles has expanded with *positive psychology*’s call for more research on human flourishing and its attempt to discover and promote traits that help people to thrive.

P-7 What are psychology’s levels of analysis and related perspectives?

The *biopsychosocial approach* integrates information from three differing but complementary *levels of analysis*: biological, psychological, and social-cultural. This approach offers a more complete understanding than could usually be reached by relying on only one of psychology’s current theoretical perspectives (neuroscience, evolutionary, behavior genetics, psychodynamic, behavioral, cognitive, and social-cultural).

P-8 What are psychology’s main subfields?

Within the science of psychology, researchers may conduct *basic research* to increase the field’s knowledge base (often in biological, developmental, cognitive, personality, and social psychology) or *applied research* to solve practical problems (in industrial-organizational psychology and other areas). Those who engage in psychology as a helping profession may assist people as *counseling psychologists*, helping people with challenges and crises (including academic, vocational, and relationship issues) and to improve their personal and social functioning, or as *clinical psychologists*, assessing and treating people with mental, emotional, and behavior disorders. (*Psychiatrists* also assess and treat people with disorders, but as medical doctors, they may prescribe drugs in

addition to psychotherapy.) *Community psychologists* work to create healthy social and physical environments (in schools, for example).

P-9 How can psychological principles help you learn, remember, and thrive?

The *testing effect* shows that learning and memory are enhanced by actively retrieving, rather than simply rereading, previously studied material. The *SQ3R* study method—survey, question, read, retrieve, and review—applies principles derived from memory research and can help you learn and remember material. Four additional tips are (1) distribute your study time; (2) learn to think critically; (3) process class information actively; and (4) overlearn. Psychological research has shown that people who live happy, thriving lives manage their time to get a full night's sleep; make space for exercise; set long-term goals, with daily aims; have a growth mindset; and prioritize relationships.

CHAPTER 1

THINKING CRITICALLY WITH PSYCHOLOGICAL SCIENCE

Research Strategies: How Psychologists Ask and Answer Questions

1-1 How does our everyday thinking sometimes lead us to a wrong conclusion?

Our everyday thinking can lead us astray because of three phenomena. *Hindsight bias* (the “I-knew-it-all-along phenomenon”) is the tendency to believe, after learning an outcome, that we would have foreseen it. Overconfidence is often the result of our readiness to be more confident than correct. These tendencies, along with our eagerness to perceive patterns in random events, lead us to overestimate the weight of commonsense thinking. Although limited by the testable questions it can address, scientific inquiry can help us overcome such biases and shortcomings.

1-2 How do theories advance psychological science?

Psychological *theories* apply an integrated set of principles to organize observations and to generate *hypotheses*. By testing their hypotheses, researchers can confirm, reject, or revise their theories. To enable other researchers to *replicate* the studies, researchers report them using precise *operational definitions* of their procedures and concepts. If others achieve similar results, confidence in the conclusion will be greater.

1-3 How do psychologists use case studies, naturalistic observations, and surveys to observe and describe behavior, and why is random sampling important?

Descriptive methods, which include *case studies*, *naturalistic observations*, and *surveys*, show us what can happen, and they may offer ideas for further study. The best basis for generalizing about a *population* is a representative sample; in a *random sample*, every person in the entire population being studied has an equal chance of participating. Descriptive methods describe but do not *explain* behavior; they cannot show cause and effect because researchers cannot control variables.

1-4 What does it mean when we say two things are correlated, and what are positive and negative correlations?

Correlation is the degree to which two variables are related, and how well one predicts

the other. In a positive correlation, two *variables* increase or decrease together; in a negative correlation, one variable increases as the other decreases. The strength and direction of their relationship is expressed as a *correlation coefficient*, which ranges from +1.00 (a perfect positive correlation) through 0 (no correlation) to −1.00 (a perfect negative correlation). The relationship may be displayed in a *scatterplot*, in which each dot represents a value for the two variables.

1-5 What are illusory correlations, and what is regression toward the mean?

Illusory correlations are random events that we notice and falsely assume are related. *Regression toward the mean* is the tendency for extreme or unusual scores to fall back (regress) toward their average.

1-6 Why do correlations enable prediction but not cause-effect explanation?

Correlations enable prediction because they show how two factors are related—either positively or negatively. A correlation can indicate the possibility of a cause-effect relationship, but it does not prove the direction of the influence, or whether an underlying third factor may explain the correlation.

1-7 What are the characteristics of experimentation that make it possible to isolate cause and effect?

To discover cause-effect relationships, psychologists conduct *experiments*, manipulating one or more variables of interest and controlling other variables. Using *random assignment*, they can minimize *confounding variables*, such as preexisting differences between the *experimental group* (exposed to the treatment) and the *control group* (not given the treatment). The *independent variable* is the factor the experimenter manipulates to study its effect; the *dependent variable* is the factor the experimenter measures to discover any changes occurring in response to the manipulation of the independent variable. Studies may use a *double-blind procedure* to avoid the *placebo effect* and researcher bias.

1-8 How would you know which research design to use?

Psychological scientists design studies and choose research methods that will best provide meaningful results. Researchers generate testable questions, and then carefully consider the best design to use in studying those questions (experimental, correlational, case study, naturalistic observation, twin study, longitudinal, or cross-sectional). Next, psychologists measure the variables they are studying, and finally they interpret their results, keeping possible confounding variables in mind. (The online Immersive Learning “How Would You Know?” research activities allow you to play the role of the researcher, making choices about the best ways to test interesting questions.)

1-9 How can simplified laboratory conditions illuminate everyday life?

Researchers intentionally create a controlled, artificial environment in the laboratory to

test general theoretical principles. It is the general principles—not the specific findings—that help explain everyday behaviors.

1-10 Why do psychologists study animals, and what ethical guidelines safeguard human and animal research participants? How do psychologists' values influence psychology?

Some psychologists are primarily interested in animal behavior; others want to better understand the physiological and psychological processes shared by humans and other species. Government agencies have established standards for animal care and housing. Professional associations and funding agencies also have guidelines for protecting animals' well-being. The APA ethics code outlines standards for safeguarding human participants' well-being, including obtaining their *informed consent* and *debriefing* them later. Psychologists' values influence their choice of research topics, their theories and observations, their labels for behavior, and their professional advice. Applications of psychology's principles have been used mainly in the service of humanity.

Statistical Reasoning in Everyday Life

1-11 How do we describe data using three measures of central tendency, and what is the relative usefulness of the two measures of variation?

Researchers use descriptive statistics to measure and describe characteristics of groups under study. A measure of central tendency is a single score that represents a whole set of scores. Three such measures that we use to describe data are the *mode* (the most frequently occurring score), the *mean* (the arithmetic average), and the *median* (the middle score in a group of data). Measures of central tendency neatly summarize data; measures of variation tell us how diverse data are. Two measures of variation are the *range* (which describes the gap between the highest and lowest scores) and the *standard deviation* (which states how much scores vary around the mean, or average, score). Scores often form a *normal* (or bell-shaped) *curve*.

1-12 How do we know whether an observed difference can be generalized to other populations?

Researchers use inferential statistics (which include ways of determining the reliability and significance of an observed difference between the results for different groups) to determine if results can be generalized to a larger population. Reliable differences are based on samples that are representative of the larger population being studied, that demonstrate low variability, on average, and that consist of many cases. We can say that an observed difference has *statistical significance* if the sample averages are reliable, and when the difference between them is large.

CHAPTER 2

THE BIOLOGY OF MIND

Neural and Hormonal Systems

2-1 Why are psychologists concerned with human biology?

Psychologists working from a *biological* perspective study the links between biology and behavior. We are biopsychosocial systems, in which biological, psychological, and social-cultural factors interact to influence behavior.

2-2 How do biology and experience interact?

Plasticity enables our brain to adjust to new experiences, thereby being sculpted by both genes and life. While this is a lifelong ability, plasticity is greatest in childhood. With practice, our brain develops unique patterns that reflect our life experiences.

2-3 What are neurons, and how do they transmit information?

Neurons are the elementary components of the nervous system, the body's speedy electrochemical information system. A neuron, consisting of a *cell body* and its branching fibers, receives signals through its often bushy, branching *dendrites* and sends signals through its *axons*. Some axons are encased in a *myelin sheath*, which enables faster transmission. *Glial cells* support, nourish, and protect neurons and also play a role in learning, thinking, and memory. If the combined signals received by a neuron exceed a minimum *threshold*, the neuron fires, transmitting an electrical impulse (the *action potential*) down its axon by means of a chemistry-to-electricity process. The neuron's reaction is an *all-or-none process*.

2-4 How do nerve cells communicate with other nerve cells?

When action potentials reach the end of an axon (the axon terminals), they stimulate the release of *neurotransmitters*. These chemical messengers carry a message from the sending neuron across a *synapse* to receptor sites on a receiving neuron. The sending neuron, in a process called *reuptake*, then normally reabsorbs the excess neurotransmitter molecules in the synaptic gap. If incoming signals are strong enough, the receiving neuron generates its own action potential and relays the message to other cells.

2-5 How do neurotransmitters influence behavior, and how do drugs and other chemicals affect neurotransmission?

Neurotransmitters travel designated pathways in the brain and may influence specific behaviors and emotions. Acetylcholine (ACh) enables muscle action, learning, and memory. *Endorphins* are natural opiates released in response to pain and exercise. Drugs

and other chemicals affect brain chemistry at synapses. *Agonists* increase a neurotransmitter's action, and may do so in various ways. *Antagonists* decrease a neurotransmitter's action by blocking production or release.

2-6 What are the functions of the nervous system's main divisions, and what are the three main types of neurons?

The *central nervous system (CNS)*—the brain and the spinal cord—is the *nervous system's* decision maker. The *peripheral nervous system (PNS)*, which connects the CNS to the rest of the body by means of *nerves*, gathers information and transmits CNS decisions to the rest of the body. The two main PNS divisions are the *somatic nervous system* (which enables voluntary control of the skeletal muscles) and the *autonomic nervous system* (which controls involuntary muscles and glands by means of its *sympathetic* and *parasympathetic* divisions). The three types of neurons cluster into working networks: (1) *Sensory (afferent) neurons* carry incoming information from the body's tissues and sensory receptors to the brain and spinal cord. (2) *Motor (efferent) neurons* carry outgoing information from the brain and spinal cord to the muscles and glands. (3) *Interneurons* communicate within the brain and spinal cord and process information between the sensory inputs and motor outputs.

2-7 How does the endocrine system transmit information and interact with the nervous system?

The *endocrine system* secretes *hormones* into the bloodstream, where they travel through the body and affect other tissues, including the brain. The endocrine system's master gland, the *pituitary*, influences hormone release by other glands, including the *adrenal glands*. In an intricate feedback system, the brain's hypothalamus influences the pituitary gland, which influences other glands, which release hormones, which in turn influence the brain.

Tools of Discovery, Older Brain Structures, and the Limbic System

2-8 How do neuroscientists study the brain's connections to behavior and mind?

Clinical observations and *lesioning* reveal the general effects of brain damage. Electrical, chemical, or magnetic stimulation can also reveal aspects of information processing in the brain. *MRI* scans show anatomy. *EEG*, *MEG*, *PET*, and *fMRI (functional MRI)* recordings reveal brain function.

2-9 What structures make up the brainstem, and what are the functions of the brainstem, thalamus, reticular formation, and cerebellum?

The *brainstem*, the oldest part of the brain, is responsible for automatic survival functions. Its components are the *medulla* (which controls heartbeat and breathing), the *pons* (which helps coordinate movements and control sleep), and the *reticular formation* (which filters incoming stimuli, relays information to other brain areas, and affects arousal). The *thalamus*, sitting above the brainstem, acts as the brain's sensory control center. The *cerebellum*, attached to the rear of the brainstem, coordinates muscle movement and balance and enables nonverbal learning and memory.

2-10 What are the limbic system's structures and functions?

The *limbic system* is linked to emotions, memory, and drives. Its neural centers include the *amygdala* (involved in responses of aggression and fear); the *hypothalamus* (directs various bodily maintenance functions, helps govern the endocrine system, and is linked to emotion and reward); and the *hippocampus* (helps process explicit, conscious memories). The hypothalamus controls the pituitary (the “master gland”) by stimulating it to trigger the release of hormones.

The Cerebral Cortex

2-11 What four lobes make up the cerebral cortex, and what are the functions of the motor cortex, somatosensory cortex, and association areas?

The *cerebral cortex* has two hemispheres, and each hemisphere has four lobes: the *frontal*, *parietal*, *occipital*, and *temporal*. Each lobe performs many functions and interacts with other areas of the cortex. The *motor cortex*, at the rear of the frontal lobes, controls voluntary movements. The *somatosensory cortex*, at the front of the parietal lobes, registers and processes body touch and movement sensations. Body parts requiring precise control (in the motor cortex) or those that are especially sensitive (in the somatosensory cortex) occupy the greatest amount of space. Most of the brain's cortex—the major portion of each of the four lobes—is devoted to uncommitted *association areas*, which integrate information involved in higher mental functions such as learning, remembering, thinking, and speaking. Our mental experiences arise from coordinated brain activity.

2-12 Do we really use only 10 percent of our brain?

The unresponsiveness of our association areas to electrical probing led to the false claim that we only use 10 percent of our brain, but these vast areas of the brain are responsible for interpreting, integrating, and acting on sensory information and linking it with stored memories. Evidence from brain damage shows that the neurons in association areas are busy with higher mental functions; a bullet would not land in an “unused” area.

2-13 To what extent can a damaged brain reorganize itself, and what is

neurogenesis?

While brain and spinal cord neurons usually do not regenerate, some neural tissue can reorganize in response to damage. The damaged brain may demonstrate plasticity, especially in young children, as new pathways are built and functions migrate to other brain regions. Reassignment of functions to different areas of the brain may also occur in blindness and deafness, or as a result of damage and disease. The brain sometimes mends itself by forming new neurons, a process known as *neurogenesis*.

2-14 What do split brains reveal about the functions of our two brain hemispheres?

Split-brain research (experiments on people with a severed *corpus callosum*) has confirmed that in most people, the left hemisphere is the more verbal. The right hemisphere excels in visual perception, perceiving emotion, and making inferences, and helps us modulate our speech and orchestrate our self-awareness. Studies of healthy people with intact brains confirm that each hemisphere makes unique contributions to the integrated functioning of the brain.

CHAPTER 3

CONSCIOUSNESS AND THE TWO-TRACK MIND

Basic Consciousness Concepts

3-1 What is the place of consciousness in psychology's history?

After initially claiming consciousness as its area of study in the nineteenth century, psychologists had abandoned it in the first half of the twentieth century, turning instead to the study of observable behavior because they believed consciousness was too difficult to study scientifically. Since 1960, under the influence of cognitive psychology, neuroscience, and *cognitive neuroscience*, our awareness of ourselves and our environment—our *consciousness*—has reclaimed its place as an important area of research.

3-2 How does selective attention direct our perceptions?

We *selectively attend* to, and process, a very limited portion of incoming information, blocking out much and often shifting the spotlight of our attention from one thing to another. Focused intently on one task, we often display *inattentional blindness* to other events, including *change blindness* to changes around us.

3-3 What is the *dual processing* being revealed by today's cognitive neuroscience?

Scientists studying the brain mechanisms underlying consciousness and cognition have discovered that the mind processes information on two separate tracks, one operating at a conscious level (*sequential processing*) and the other at an unconscious level (*parallel processing*). Parallel processing takes care of the routine business, while sequential processing is best for solving new problems that require our attention. Together, this *dual processing*—conscious and unconscious—affects our perception, memory, attitudes, and other cognitions.

Sleep and Dreams

3-4 What is *sleep*?

Sleep is the periodic, natural loss of consciousness—as distinct from unconsciousness

resulting from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.)

3-5 How do our biological rhythms influence our daily functioning?

Our bodies have an internal biological clock, roughly synchronized with the 24-hour cycle of night and day. This *circadian rhythm* appears in our daily patterns of body temperature, arousal, sleeping, and waking. Age and experience can alter these patterns, resetting our biological clock.

3-6 What is the biological rhythm of our sleeping and dreaming stages?

Younger adults cycle through four distinct sleep stages about every 90 minutes. (The sleep cycle repeats more frequently for older adults.) Leaving the *alpha waves* of the awake, relaxed stage, we descend into the irregular brain waves of non-REM stage 1 (NREM-1) sleep, often with *hallucinations*. NREM-2 sleep (in which we spend about half our sleep time) follows, lasting about 20 minutes, with its characteristic sleep spindles. We then enter NREM-3 sleep, lasting about 30 minutes, with large, slow *delta waves*. About an hour after falling asleep, we ascend from our initial sleep dive and begin periods of *REM* (rapid eye movement) *sleep*. REM sleep is described as a paradoxical sleep stage because of internal arousal but external calm (near paralysis). It includes most dreaming, and lengthens as the night goes on. During a normal night's sleep, NREM-3 sleep shortens and REM and NREM-2 sleep lengthens.

3-7 How do biology and environment interact in our sleep patterns?

Our biology—our circadian rhythm as well as our age and our body's production of melatonin (influenced by the brain's *suprachiasmatic nucleus*)—interacts with cultural expectations and individual behaviors to determine our sleeping and waking patterns. Being bathed in (or deprived of) light disrupts our 24-hour biological clock; night-shift workers may experience chronic desynchronization.

3-8 What are sleep's functions?

Sleep may have played a protective role in human evolution by keeping people safe during potentially dangerous periods. Sleep also helps restore and repair damaged neurons. Sleep consolidates our memories by replaying recent learning and strengthening neural connections. Sleep promotes creative problem solving the next day. During slow-wave sleep, the pituitary gland secretes a growth hormone necessary for muscle development.

3-9 How does sleep loss affect us, and what are the major sleep disorders?

Sleep deprivation causes fatigue and irritability, and it impairs concentration, productivity, and memory consolidation. It can also lead to depression, obesity, joint pain, a suppressed immune system, and slowed performance (with greater vulnerability to accidents). Sleep disorders include *insomnia* (recurring wakefulness); *narcolepsy* (sudden uncontrollable sleepiness, sometimes lapsing directly into REM sleep); *sleep apnea* (the repeated stopping of breathing while asleep; associated with obesity,

especially in men); *night terrors* (high arousal and the appearance of being terrified; NREM-3 disorder found mainly in children); sleepwalking (NREM-3 disorder also found mainly in children); and sleepwalking.

3-10 What do we dream, and what functions have theorists proposed for dreams?

We usually *dream* of ordinary events and everyday experiences, most involving some anxiety or misfortune. Fewer than 10 percent of dreams among men (and fewer still among women) have any sexual content. Most dreams occur during REM sleep; those that happen during NREM sleep tend to be vague fleeting images. There are five major views of the function of dreams. (1) Freud's wish-fulfillment: Dreams provide a psychic "safety valve," with *manifest content* (story line) acting as a censored version of *latent content* (underlying meaning that gratifies our unconscious wishes). (2) Information-processing: Dreams help us sort out the day's events and consolidate them in memory. (3) Physiological function: Regular brain stimulation may help develop and preserve neural pathways in the brain. (4) Neural activation: The brain attempts to make sense of neural static by weaving it into a story line. (5) Cognitive development: Dreams reflect the dreamers' level of development—their knowledge and understanding. Most sleep theorists agree that REM sleep and its associated dreams serve an important function, as shown by the *REM rebound* that occurs following REM deprivation in humans and other species.

Drugs and Consciousness

3-11 What are substance use disorders?

Those with a *substance use disorder* experience continued substance craving and use despite significant life disruption and/or physical risk. *Psychoactive drugs* alter perceptions and moods.

3-12 What roles do tolerance, withdrawal, and addiction play in substance use disorders, and how has the concept of *addiction* changed?

Psychoactive drugs may produce *tolerance*—requiring larger doses to achieve the desired effect—and *withdrawal*—significant discomfort, due to strong addictive cravings, accompanying attempts to quit. Addiction prompts users to crave the drug and to continue use despite known adverse consequences. Therapy or group support may help; it helps to believe that addictions are controllable and that people can change. Although psychologists try to avoid overuse of the term "addiction" to label driven, excessive behaviors, there are some behavior addictions (such as gambling disorder) in which behaviors become compulsive and dysfunctional.

3-13 What are *depressants*, and what are their effects?

Depressants, such as alcohol, *barbiturates*, and the *opiates*, reduce neural activity and slow body functions. Alcohol disinhibits, increasing the likelihood that we will act on our impulses, whether harmful or helpful. It also impairs judgment by slowing neural processing, disrupts memory processes by suppressing REM sleep, and reduces self-awareness and self-control. User expectations strongly influence alcohol's behavioral effects. Alcohol can shrink the brain in those with *alcohol use disorder* (marked by tolerance, withdrawal if use is suspended, and a drive to continue problematic use).

3-14 What are *stimulants*, and what are their effects?

Stimulants—including caffeine, nicotine, cocaine, the amphetamines, methamphetamine, and Ecstasy—excite neural activity and speed up body functions, triggering energy and mood changes. All are highly addictive. *Nicotine's* effects make tobacco product use a difficult habit to kick, yet repeated attempts to quit seem to pay off. *Cocaine* gives users a fast high, followed shortly by a crash. Its risks include cardiovascular stress and suspiciousness. *Amphetamines* stimulate neural activity, leading to heightened energy and mood. *Methamphetamine* use may permanently reduce dopamine production. *Ecstasy (MDMA)* is a combined stimulant and mild hallucinogen that produces euphoria and feelings of intimacy. Its users risk immune system suppression, permanent damage to mood and memory, and (if taken during physical activity) dehydration and escalating body temperatures.

3-15 What are *hallucinogens*, and what are their effects?

Hallucinogens, such as *LSD* and marijuana, distort perceptions and evoke hallucinations. The user's mood and expectations influence the effects of *LSD*, but common experiences are hallucinations and emotions varying from euphoria to panic. Marijuana's main ingredient, *THC*, may trigger feelings of disinhibition, euphoria, relaxation, relief from pain, and intense sensitivity to sensory stimuli, but may increase the risk of psychological disorders and lead to impaired learning and memory.

3-16 Why do some people become regular users of consciousness-altering drugs?

Some people may be biologically vulnerable to particular drugs. Psychological factors (such as stress, depression, and hopelessness) and social factors (such as peer pressure) combine to lead many people to experiment with—and sometimes become addicted to—drugs. Cultural and ethnic groups have differing rates of drug use. Each type of influence—biological, psychological, and social-cultural—offers a possible path for drug misuse prevention and treatment programs.

CHAPTER 4

NATURE, NURTURE, AND HUMAN DIVERSITY

Behavior Genetics: Predicting Individual Differences

4-1 What are *chromosomes*, *DNA*, *genes*, and the human *genome*? How do behavior geneticists explain our individual differences?

Genes are the biochemical units of heredity that make up *chromosomes*, the threadlike coils of *DNA*. When genes are expressed, they provide the code for creating the proteins that form our body's building blocks. Most human traits are influenced by many genes acting together. The human *genome* is the shared genetic profile that distinguishes humans from other species, consisting at an individual level of all the genetic material in an organism's chromosomes. *Behavior geneticists* study the relative power and limits of genetic (our *heredity*) and *environmental* influences on behavior. Most of our differing traits are influenced by many genes, and by the interaction of our individual environments with these genetic predispositions.

4-2 How do twin and adoption studies help us understand the effects and interactions of nature and nurture?

Studies of *identical (monozygotic) twins* versus *fraternal (dizygotic) twins*, separated twins, and biological versus adoptive relatives allow researchers to consider the effects of shared environment and shared genes, which sheds light on how nature and nurture influence our traits. Shared family environments have surprisingly little effect on personality, though parenting does influence other factors.

4-3 What have psychologists learned about temperament?

The stability of *temperament*, a person's characteristic emotional reactivity and intensity, from the first weeks of life suggests a genetic predisposition. The genetic effect appears in physiological differences such as heart rate and nervous system reactivity.

4-4 What is *heritability*, and how does it relate to individuals and groups?

Heritability describes the extent to which variation among members of a group can be attributed to genes. Heritable individual differences (in traits such as height or intelligence) need not imply heritable group differences. Genes mostly explain why some people are taller than others, but not why people are taller today than they were a century ago.

4-5 How is molecular genetics research changing our understanding of

the effects of nature and nurture?

Our genetic predispositions and our surrounding environments *interact*. Environments can trigger gene activity, and genetically influenced traits can evoke responses from others. *Molecular geneticists* study the molecular structure and function of genes, including those that affect behavior. One goal of *molecular behavior genetics* is to identify specific genes—or, more often, teams of genes—that together orchestrate complex traits (such as body weight, sexual orientation, and impulsivity) or put people at risk for disorders. The field of *epigenetics* studies the molecular mechanisms by which environments can trigger or block genetic expression.

Evolutionary Psychology: Understanding Human Nature

4-6 How do evolutionary psychologists use natural selection to explain behavior tendencies?

Evolutionary psychologists seek to understand how our traits and behavior tendencies are shaped by *natural selection*, as genetic variations increasing the odds of reproducing and surviving in their particular environment are most likely to be passed on to future generations. Some variations arise from *mutations*, others from new gene combinations at conception. Humans share a genetic legacy and are predisposed to behaviors that promoted our ancestors' survival and reproduction. Charles Darwin's theory of evolution is one of biology's fundamental organizing principles. He anticipated today's application of evolutionary principles in psychology.

4-7 How might an evolutionary psychologist explain male-female differences in sexuality and mating preferences?

Women tend to be more selective than men when choosing sexual partners. Evolutionary psychologists reason that men's attraction to multiple healthy, fertile-appearing partners increases their chances of spreading their genes widely. Because women incubate and nurse babies, they increase their own and their children's chances of survival by searching for mates with the potential for long-term investment in their joint offspring.

4-8 What are the key criticisms of evolutionary explanations of human sexuality, and how do evolutionary psychologists respond?

Critics argue that evolutionary psychologists start with an effect and work backward to an explanation, minimize contemporary social and cultural influences (including learned *social scripts*), and relieve people from taking responsibility for their sexual behavior. Evolutionary psychologists respond that they recognize the importance of social and cultural influences, but note the value in testable predictions based on evolutionary

principles: Understanding our predispositions can help us overcome them.

Culture, Gender, and Other Environmental Influences

4-9 How do early experiences modify the brain?

As a child's brain develops, neural connections grow more numerous and complex. Experiences then prompt a pruning process, in which unused connections weaken and heavily used ones strengthen. Early childhood is an important period for shaping the brain, but thanks to plasticity the brain modifies itself throughout our lives in response to our learning.

4-10 In what ways do parents and peers shape children's development?

Family environment and parental expectations can affect children's motivation and future success. Personality, however, is mostly not attributable to the effects of nurture. As children attempt to fit in with their peers, they tend to adopt their culture—styles, accents, slang, attitudes. By choosing their children's neighborhoods and schools, parents exert some influence over peer group culture.

4-11 How does culture affect our behavior?

A *culture* is an enduring set of behaviors, ideas, attitudes, values, and traditions shared by a group and transmitted from one generation to the next. Cultural *norms* are understood rules that inform members of a culture about accepted and expected behaviors. Cultures differ across time and space.

4-12 How do individualist and collectivist cultures differ in their values and goals?

Although individuals vary, different cultures tend to emphasize either individualism or collectivism. Cultures based on self-reliant *individualism* tend to value personal independence and individual achievement. They define identity in terms of self-esteem, personal goals and attributes, and personal rights and liberties. Cultures based on socially connected *collectivism* tend to value group goals, social identity, and commitments. They define identity in terms of interdependence, tradition, and harmony.

4-13 How does the meaning of *gender* differ from the meaning of *sex*?

In psychology, *gender* refers to the socially and culturally constructed expectations about what it means to be a boy, girl, man, or woman. *Sex* refers to our biological status as male or female, defined by our chromosomes and anatomy. We might say that our body defines our sex, while our mind defines our gender.

4-14 What are some ways in which males and females tend to be alike and to differ?

We are more alike than different, thanks to our similar genetic makeup—we see, learn, and remember similarly, with comparable creativity, intelligence, and emotions. Males and females do differ in height, age of onset of puberty, life expectancy, and vulnerability to certain disorders. Men admit to more *aggression* than women do, and they are more likely to be physically (rather than *relationally*) aggressive. Women focus more on social connectedness; they are more interdependent, and they “tend and befriend.”

4-15 What factors contribute to gender bias in the workplace?

Differences in male-female perceptions, compensation, and family responsibility both influence and reflect workplace gender bias. In most societies, men have more social power, and their leadership style tends to be directive, whereas women’s tends to be more democratic. In their everyday behaviors and interactions, men tend to act more assertive and opinionated; women tend to act more supportive and apologetic.

4-16 How do sex hormones influence prenatal and adolescent sexual development, and what is an *intersex* condition?

Both sex chromosomes and sex hormones influence development. About seven weeks after conception, a gene on the *Y chromosome* from the father—who can contribute either this or an *X chromosome* (the mother always contributes the latter)—triggers the production of *testosterone*. This promotes male sex organ development. During the fourth and fifth prenatal months, sex hormones bathe the fetal brain, with different patterns developing due to the male’s greater testosterone and the female’s ovarian hormones. Prenatal exposure of females to unusually high levels of male hormones can later dispose them to more male-typical interests. Another flood of hormones occurs in *puberty*, triggering a growth spurt, the development of *primary* and *secondary sex characteristics*, and the landmark events of *menarche* and *spermarche*. *Intersex* individuals are born with intermediate or unusual combinations of male and female chromosomes, hormones, and anatomy.

4-17 How do gender roles and gender identity differ?

Gender roles, the behaviors a culture expects from its men and women, vary across place and time. *Social learning theory* proposes that we learn *gender identity*—our personal sense of being male, female, or some combination of the two—as we learn other things: through reinforcement, punishment, and observation. Critics argue that cognition also plays a role, as *gender typing* varies among children. We seem to conform in ways that feel comfortable to us, whether that means taking on a male role, female role, or blend of the two (*androgyny*). *Transgender* people’s gender identity or expression differs from the behaviors or traits considered typical for their birth-designated sex. Their sexual orientation may be heterosexual, homosexual, bisexual, or asexual.

4-18 How do nature, nurture, and our own choices influence gender roles?

Individual development results from the interaction of biological, psychological, and

social-cultural influences. Biological influences include our shared human genome; individual variations; prenatal environment; and sex-related genes, hormones, and physiology. Psychological influences include gene-environment interactions; the effect of early experiences on neural networks; responses evoked by our own characteristics, such as gender and temperament; and personal beliefs, feelings, and expectations. Social-cultural influences include parental and peer influences; cultural traditions and values; and cultural gender norms.

CHAPTER 5

DEVELOPING THROUGH THE LIFE SPAN

Developmental Issues, Prenatal Development, and the Newborn

5-1 What three issues have engaged developmental psychologists?

Developmental psychologists study physical, cognitive, and social changes throughout the life span. They focus on three issues: nature and nurture (the interaction between our genetic inheritance and our experiences); continuity and stages (which aspects of development are gradual and continuous and which change relatively abruptly); and stability and change (whether our traits endure or change as we age).

5-2 What is the course of prenatal development, and how do *teratogens* affect that development?

The life cycle begins at conception, when one sperm cell unites with an egg to form a *zygote*. The zygote's inner cells become the *embryo*, and the outer cells become the placenta. In the next 6 weeks, body organs begin to form and function, and by 9 weeks, the *fetus* is recognizably human. *Teratogens* are potentially harmful agents that can pass through the placenta and harm the developing embryo or fetus, as happens with *fetal alcohol syndrome*.

5-3 What are some newborn abilities, and how do researchers explore infants' mental abilities?

Babies are born with sensory equipment and reflexes that facilitate their survival and their social interactions with adults. For example, they quickly learn to discriminate their mother's smell, and they prefer the sound of human voices. Researchers use techniques that test *habituation*, such as the novelty-preference procedure, to explore infants' abilities.

Infancy and Childhood

5-4 During infancy and childhood, how do the brain and motor skills develop?

The brain's nerve cells are sculpted by heredity and experience. As a child's brain

develops, neural connections grow more numerous and complex. Experiences then trigger a pruning process, in which unused connections weaken and heavily used ones strengthen. Early childhood is an important period for shaping the brain, but our brain modifies itself in response to our learning throughout life. In childhood, complex motor skills—sitting, standing, walking—develop in a predictable sequence, though the timing of that sequence is a function of individual *maturation* and culture. We have few or no conscious memories of events occurring before about age 4. This infantile amnesia occurs in part because major brain areas have not yet matured.

5-5 From the perspectives of Piaget, Vygotsky, and today's researchers, how does a child's mind develop?

In his theory of *cognitive* development, Jean Piaget proposed that children actively construct and modify their understanding of the world through the processes of *assimilation* and *accommodation*. They form *schemas* that help them organize their experiences. Progressing from the simplicity of the *sensorimotor stage* of the first two years, in which they develop *object permanence*, children move to more complex ways of thinking. In the *preoperational stage* (about age 2 to about 6 or 7), they develop a *theory of mind*. In the preoperational stage, children are *egocentric* and unable to perform simple logical operations. By about age 7, they enter the *concrete operational stage* and are able to comprehend the principle of *conservation*. By age 12, children enter the *formal operational stage* and can reason systematically. Research supports the sequence Piaget proposed, but it also shows that young children are more capable, and their development more continuous, than he believed. Lev Vygotsky's studies of child development focused on the ways a child's mind grows by interacting with the social environment. In his view, parents and caretakers provide temporary *scaffolds* enabling children to step to higher levels of thinking.

5-6 What is autism spectrum disorder?

Autism spectrum disorder (ASD) is a disorder marked by social deficiencies and repetitive behaviors, with differing levels of severity. Children with ASD have an impaired theory of mind. By age eight, 1 in 68 U.S. children now gets diagnosed with ASD (though the reported rates vary by place). The increase in diagnoses has been offset by a decrease in the number of children with a "cognitive disability" or "learning disability." Genetic influences, abnormal brain development, and the prenatal environment—especially when altered by infection, drugs, or hormones—likely contribute to ASD.

5-7 How do parent-infant attachment bonds form?

At about 8 months, soon after object permanence develops, children separated from their caregivers display *stranger anxiety*. Infants form *attachments* with caregivers who gratify biological needs but, more importantly, who are comfortable, familiar, and responsive. Many birds and other animals have a more rigid attachment process, called *imprinting*, that occurs during a *critical period*.

5-8 How have psychologists studied attachment differences, and what have they learned?

Attachment has been studied in strange situation experiments, which show that some children are securely attached and others are insecurely (anxiously or avoidantly) attached. Infants' differing attachment styles reflect both their individual temperament and the responsiveness of their parents and child-care providers. Adult relationships seem to reflect the attachment styles of early childhood, lending support to Erik Erikson's idea that *basic trust* is formed in infancy by our experiences with responsive caregivers.

5-9 How does childhood neglect or abuse affect children's attachments?

Most children are resilient, but those who are severely neglected by their parents, or otherwise prevented from forming attachments at an early age, may be at risk for attachment problems. Extreme trauma in childhood may alter the brain, affecting our stress responses or leaving epigenetic marks.

5-10 How do children's self-concepts develop?

Self-concept, an understanding and evaluation of who we are, emerges gradually. By 15 to 18 months, children recognize themselves in a mirror. By school age, they can describe many of their own traits, and by age 8 or 10 their self-image is stable.

5-11 What are the four main parenting styles?

The main parenting styles are authoritarian (coercive), permissive (unrestraining), negligent (uninvolved), and authoritative (confrontive).

5-12 What outcomes are associated with each parenting style?

Authoritative parenting is associated with greater self-esteem, self-reliance, self-regulation, and social competence; authoritarian parenting with lower self-esteem, less social skill, and a brain that overreacts to mistakes; permissive parenting with greater aggression and immaturity; and negligent parenting with poor academic and social outcomes. However, correlation does not equal causation (it's possible that children with positive characteristics are more likely to bring out positive parenting methods).

Adolescence

5-13 How is *adolescence* defined, and how do physical changes affect developing teens?

Adolescence is the transition period from childhood to adulthood, extending from *puberty* to social independence. Boys seem to benefit (though with risks) from “early” maturation, girls from “late” maturation. The brain's frontal lobes mature and myelin growth increases during adolescence and the early twenties, enabling improved

judgment, impulse control, and long-term planning.

5-14 How did Piaget, Kohlberg, and later researchers describe adolescent cognitive and moral development?

Piaget theorized that adolescents develop a capacity for formal operations and that this development is the foundation for moral judgment. Lawrence Kohlberg proposed a stage theory of moral reasoning, from a preconventional morality of self-interest, to a conventional morality concerned with upholding laws and social rules, to (in some people) a postconventional morality of universal ethical principles. Other researchers believe that morality lies in moral intuition and moral action as well as thinking. Kohlberg's critics note that the postconventional level is culturally limited, representing morality only from the perspective of an individualist society.

5-15 What are the social tasks and challenges of adolescence?

Erik Erikson proposed eight stages of psychosocial development across the life span. He believed we need to achieve the following challenges: trust, autonomy, initiative, competency, *identity* (in adolescence), *intimacy* (in young adulthood), generativity, and integrity. Each life stage has its own psychosocial task. Solidifying one's sense of self in adolescence means trying out a number of different roles. *Social identity* is the part of the self-concept that comes from a person's group memberships.

5-16 How do parents and peers influence adolescents?

During adolescence, parental influence diminishes and peer influence increases. Adolescents adopt their peers' ways of dressing, acting, and communicating. Parents have more influence in religion, politics, and education and career choices.

5-17 What is emerging adulthood?

Due to earlier sexual maturity and later independence, the transition from adolescence to adulthood is taking longer than it once did. *Emerging adulthood* is the period from age 18 to the mid-twenties, when many young people are not yet fully independent. This stage is found mostly in today's Western cultures.

Adulthood

5-18 What physical changes occur during middle and late adulthood?

Muscular strength, reaction time, sensory abilities, and cardiac output begin to almost imperceptibly decline in the mid-twenties; this downward trajectory accelerates through middle and late adulthood. Women's period of fertility ends with *menopause* around age 50; men experience a more gradual decline. In late adulthood, the immune system weakens, increasing susceptibility to life-threatening illnesses. Chromosome tips (telomeres) wear down, reducing the chances of normal genetic replication. But for some, longevity-supporting genes, low stress, and good health habits enable better health

in later life.

5-19 How does memory change with age?

Recall begins to decline, especially for meaningless information, but recognition memory remains strong. Older adults rely more on time management and memory cues to remember time-based and habitual tasks. Developmental researchers study age-related changes such as in memory with *cross-sectional studies* (comparing people of different ages at one point in time) and *longitudinal studies* (retesting the same people over a period of years). “Terminal decline” describes the cognitive decline in the final few years of life.

5-20 How do neurocognitive disorders and Alzheimer’s disease affect cognitive ability?

Neurocognitive disorders (NCDs) are acquired (not lifelong) disorders marked by cognitive deficits, which are often related to Alzheimer’s disease, brain injury or disease, or substance abuse. This damage to brain cells results in the erosion of mental abilities that is not typical of normal aging. *Alzheimer’s disease* causes the deterioration of memory, then reasoning. After 5 to 20 years, the person becomes emotionally flat, disoriented, disinhibited, incontinent, and finally mentally vacant.

5-21 What themes and influences mark our social journey from early adulthood to death?

Adults do not progress through an orderly sequence of age-related social stages. Chance events can determine life choices. The *social clock* is a culture’s preferred timing for events such as marriage, parenthood, and retirement. Adulthood’s dominant themes are love and work (Erikson’s intimacy and generativity).

5-22 How does our well-being change across the life span?

Our self-confidence and sense of identity tend to strengthen across the life span. Surveys show that life satisfaction is unrelated to age until the terminal decline phase. Positive emotions increase after midlife and negative ones decrease; with age come fewer extremes of emotion and mood.

5-23 A loved one’s death triggers what range of reactions?

People do not grieve in predictable stages, as was once supposed. Strong expressions of emotion do not purge grief, and bereavement therapy is not significantly more effective than grieving without such aid. Life can be affirmed even at death, especially for those who experience what Erikson called a sense of integrity—a feeling that one’s life has been meaningful.

CHAPTER 6

SENSATION AND PERCEPTION

Basic Concepts of Sensation and Perception

6-1 What are *sensation* and *perception*? What do we mean by *bottom-up processing* and *top-down processing*?

Sensation is the process by which our *sensory receptors* and nervous system receive and represent stimulus energies from our environment. *Perception* is the process of organizing and interpreting this information, enabling recognition of meaningful events. Sensation and perception are one continuous process. *Bottom-up processing* is sensory analysis that begins at the entry level, with information flowing from the sensory receptors to the brain. *Top-down processing* is information processing guided by high-level mental processes, as when we construct perceptions by filtering information through our experience and expectations.

6-2 What three steps are basic to all our sensory systems?

Our senses (1) receive sensory stimulation (often using specialized receptor cells); (2) transform that stimulation into neural impulses; and (3) deliver the neural information to the brain. *Transduction* is the process of converting one form of energy into another. Researchers in *psychophysics* study the relationships between stimuli's physical characteristics and our psychological experience of them.

6-3 How do absolute thresholds and difference thresholds differ?

Our *absolute threshold* for any stimulus is the minimum stimulation necessary for us to be consciously aware of it 50 percent of the time. *Signal detection theory* predicts how and when we will detect a faint stimulus amid background noise. Individual absolute thresholds vary, depending on the strength of the signal and also on our experience, expectations, motivation, and alertness. Our *difference threshold* (also called the *just noticeable difference*, or *jnd*) is the difference we can discern between two stimuli 50 percent of the time. *Weber's law* states that two stimuli must differ by a constant minimum percentage (not a constant amount) to be perceived as different.

6-4 How are we affected by subliminal stimuli?

We do sense some stimuli *subliminally*—less than 50 percent of the time—and can be affected by these sensations. But although we can be *primed*, subliminal sensations have no powerful, enduring influence.

6-5 What is the function of sensory adaptation?

Sensory adaptation (our diminished sensitivity to constant or routine odors, sounds, and touches) focuses our attention on informative changes in our environment.

6-6 How do our expectations, contexts, motivation, and emotions influence our perceptions?

Perceptual set is a mental predisposition that functions as a lens through which we perceive the world. Our learned concepts (schemas) prime us to organize and interpret ambiguous stimuli in certain ways. Our motivation, as well as our physical and emotional context, can create expectations and color our interpretation of events and behaviors.

Vision: Sensory and Perceptual Processing

6-7 What are the characteristics of the energy that we see as visible light? What structures in the eye help focus that energy?

What we see as light is only a thin slice of the broad spectrum of electromagnetic energy. The portion visible to humans extends from the blue-violet to the red light wavelengths. After entering the eye through the cornea, passing through the pupil and iris, and being focused by a lens, light energy particles strike the eye's inner surface, the *retina*. The *hue* we perceive in a light depends on its *wavelength*, and its brightness depends on its *intensity*.

6-8 How do the rods and cones process information, and what is the path information travels from the eye to the brain?

Light entering the eye triggers chemical changes that convert light energy into neural impulses. *Cones* and *rods* at the back of the retina each provide a special sensitivity—cones to detail and color, rods to faint light and peripheral motion. After processing by bipolar and ganglion cells, neural impulses travel from the retina through the *optic nerve* to the thalamus, and on to the visual cortex.

6-9 How do we perceive color in the world around us?

According to the *Young-Helmholtz trichromatic (three-color) theory*, the retina contains three types of color receptors. Contemporary research has found three types of cones, each most sensitive to the wavelengths of one of the three primary colors of light (red, green, or blue). According to *Hering's opponent-process theory*, there are three additional color processes (red-versus-green, blue-versus-yellow, black-versus-white). Research has confirmed that, en route to the brain, neurons in the retina and the thalamus code the color-related information from the cones into pairs of opponent colors. These two theories, and the research supporting them, show that color processing occurs in two stages.

6-10 Where are feature detectors located, and what do they do?

Feature detectors, specialized nerve cells in the visual cortex, respond to specific features of the visual stimulus, such as shape, angle, or movement. Feature detectors pass information on to other cortical areas, where supercell clusters respond to more complex patterns.

6-11 How does the brain use parallel processing to construct visual perceptions?

Through *parallel processing*, the brain handles many aspects of vision (color, movement, form, and depth) simultaneously. Other neural teams integrate the results, comparing them with stored information and enabling perceptions.

6-12 How did the Gestalt psychologists understand perceptual organization, and how do figure-ground and grouping principles contribute to our perceptions?

Gestalt psychologists searched for rules by which the brain organizes fragments of sensory data into *gestalts*, or meaningful forms. In pointing out that the whole may exceed the sum of its parts, they noted that we filter sensory information and construct our perceptions. To recognize an object, we must first perceive it (see it as a *figure*) as distinct from its surroundings (the *ground*). We bring order and form to stimuli by organizing them into meaningful *groups*, following such rules as proximity, continuity, and closure.

6-13 How do we use binocular and monocular cues to see the world in three dimensions, and how do we perceive motion?

Depth perception is our ability to see objects in three dimensions and judge distance. The *visual cliff* and other research demonstrate that many species perceive the world in three dimensions at, or very soon after, birth. *Binocular cues*, such as *retinal disparity*, are depth cues that rely on information from both eyes. *Monocular cues* (such as relative height, relative size, interposition, relative motion, linear perspective, and light and shadow) let us judge depth using information transmitted by only one eye. As objects move, we assume that shrinking objects are retreating and enlarging objects are approaching. The brain computes motion imperfectly, with young children especially at risk of incorrectly perceiving approaching hazards such as vehicles. A quick succession of images on the retina can create an illusion of movement, as in stroboscopic movement or the *phi phenomenon*.

6-14 How do perceptual constancies help us construct meaningful perceptions?

Perceptual constancies, such as in color, brightness (or lightness), shape, or size enable us to perceive objects as stable despite the changing image they cast on our retinas. Our brain constructs our experience of an object's color or brightness through comparisons with other surrounding objects. Knowing an object's size gives us clues to its distance; knowing its distance gives clues about its size, but we sometimes misread monocular

distance cues and reach the wrong conclusions, as in the Moon illusion.

6-15 What does research on restored vision, sensory restriction, and perceptual adaptation reveal about the effects of experience on perception?

Experience guides our perceptual interpretations. People blind from birth who gained sight after surgery lack the experience to visually recognize shapes and forms. Sensory restriction research indicates that there is a critical period for some aspects of sensory and perceptual development. Without early stimulation, the brain's neural organization does not develop normally. People given glasses that shift the world slightly to the left or right, or even upside down, experience *perceptual adaptation*. They are initially disoriented, but they manage to adapt to their new context.

The Nonvisual Senses

6-16 What are the characteristics of air pressure waves that we hear as sound?

Sound waves are bands of compressed and expanded air. Our ears detect these changes in air pressure and transform them into neural impulses, which the brain decodes as sound. Sound waves vary in amplitude, which we perceive as differing loudness, and in *frequency*, which we experience as differing *pitch*.

6-17 How does the ear transform sound energy into neural messages?

The *middle ear* is the chamber between the eardrum and *cochlea*; the *inner ear* consists of the cochlea, semicircular canals, and vestibular sacs. Sound waves traveling through the auditory canal cause tiny vibrations in the eardrum. The bones of the middle ear amplify the vibrations and relay them to the fluid-filled cochlea. Rippling of the basilar membrane, caused by pressure changes in the cochlear fluid, causes movement of the tiny hair cells, triggering neural messages to be sent (via the thalamus) to the auditory cortex in the brain. *Sensorineural hearing loss* (or nerve deafness) results from damage to the cochlea's hair cells or their associated nerves. *Conduction hearing loss* results from damage to the mechanical system that transmits sound waves to the cochlea. *Cochlear implants* can restore hearing for some people.

6-18 How do we detect loudness, discriminate pitch, and locate sounds?

Loudness is not related to the intensity of a hair cell's response, but rather to the number of activated hair cells. *Place theory* explains how we hear high-pitched sounds, and *frequency theory* explains how we hear low-pitched sounds. A combination of the two theories explains how we hear pitches in the middle range. Sound waves strike one ear sooner and more intensely than the other. To locate sounds, the brain analyzes the minute differences in the sounds received by the two ears and computes the sound's

source.

6-19 How do we sense touch?

Our sense of touch is actually several senses—pressure, warmth, cold, and pain—that combine to produce other sensations, such as “hot.”

6-20 What biological, psychological, and social-cultural influences affect our experience of pain? How do placebos, distraction, and hypnosis help control pain?

The biopsychosocial perspective views our perception of pain as the sum of biological, psychological, and social-cultural influences. Pain reflects bottom-up sensations and top-down processes. One theory of pain is that a “*gate*” in the spinal cord either opens to permit pain signals traveling up small nerve fibers to reach the brain, or closes to prevent their passage. Pain treatments often combine physical and psychological elements. Combining a placebo with distraction, and amplifying the effect with *hypnosis* (which increases our response to suggestions), can help relieve pain. *Posthypnotic suggestion* is used by some clinicians to control undesired symptoms and behavior.

6-21 In what ways are our senses of taste and smell similar, and how do they differ?

Taste and smell are both chemical senses. Taste is a composite of five basic sensations—sweet, sour, salty, bitter, and umami—and of the aromas that interact with information from the taste receptor cells of the taste buds. There are no basic sensations for smell (*olfaction*). We smell something when airborne molecules reach a tiny cluster of 20 million receptor cells at the top of each nasal cavity. Odor molecules trigger combinations of receptors, in patterns that the olfactory cortex interprets. The receptor cells send messages to the brain’s olfactory bulb, then to the temporal lobe, and to parts of the limbic system.

6-22 How do we sense our body’s position and movement?

Through *kinesthesia*, we sense the position and movement of our body parts. We monitor our head’s (and thus our body’s) position and movement, and maintain our balance, with our *vestibular sense*, which relies on the semicircular canals and vestibular sacs to sense the tilt or rotation of our head.

6-23 How does sensory interaction influence our perceptions, and what is embodied cognition?

Our senses influence one another. This *sensory interaction* occurs, for example, when the smell of a favorite food amplifies its taste. *Embodied cognition* is the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments.

6-24 What are the claims of ESP, and what have most research psychologists concluded after putting these claims to the test?

Parapsychology is the study of paranormal phenomena, including *extrasensory*

perception (ESP) and psychokinesis. The three most testable forms of ESP are telepathy (mind-to-mind communication), clairvoyance (perceiving remote events), and precognition (perceiving future events). To believe in ESP is to believe the brain is capable of perceiving without sensory input; researchers have been unable to replicate ESP phenomena under controlled conditions.

CHAPTER 7

LEARNING

Basic Learning Concepts and Classical Conditioning

7-1 How do we define *learning*, and what are some basic forms of learning?

Learning is the process of acquiring through experience new information or behaviors. In *associative learning*, we learn that certain events occur together. In classical conditioning, we learn to associate two or more *stimuli*. Automatically responding to stimuli we do not control is called *respondent behavior*. In operant conditioning, we learn to associate a response and its consequences. These associations produce *operant behaviors*. Through *cognitive learning*, we acquire mental information that guides our behavior. For example, in observational learning, we learn new behaviors by observing events and watching others.

7-2 What was behaviorism's view of learning?

Ivan Pavlov's work on classical conditioning laid the foundation for *behaviorism*, the view that psychology should be an objective science that studies behavior without reference to mental processes. The behaviorists believed that the basic laws of learning are the same for all species, including humans.

7-3 Who was Pavlov, and what are the basic components of classical conditioning?

Ivan Pavlov, a Russian physiologist, created novel experiments on learning. His early twentieth-century research over the last three decades of his life demonstrated that classical conditioning is a basic form of learning. *Classical conditioning* is a type of learning in which an organism comes to associate stimuli and anticipate events. A *UR* is an event that occurs naturally (such as salivation), in response to some stimulus. A *US* is something that naturally and automatically (without learning) triggers the unlearned response (as food in the mouth triggers salivation). A *CS* is originally an *NS* (neutral stimulus, such as a tone) that, after association with a *US* (such as food) comes to trigger a *CR*. A *CR* is the learned response (salivating) to the originally neutral (but now conditioned) stimulus.

7-4 In classical conditioning, what are the processes of acquisition, extinction, spontaneous recovery, generalization, and discrimination?

In classical conditioning, the first stage is *acquisition*, associating an NS with the US so that the NS begins triggering the CR. Acquisition occurs most readily when the NS is presented just before (ideally, about a half-second before) a US, preparing the organism for the upcoming event. This finding supports the view that classical conditioning is biologically adaptive. Through *higher-order conditioning*, a new NS can become a new CS. *Extinction* is diminished responding, which occurs if the CS appears repeatedly by itself without the US. *Spontaneous recovery* is the appearance of a formerly extinguished conditioned response, following a rest period. *Generalization* is the tendency to respond to stimuli that are similar to a CS. *Discrimination* is the learned ability to distinguish between a CS and other irrelevant stimuli.

7-5 Why does Pavlov's work remain so important?

Pavlov taught us that significant psychological phenomena can be studied objectively, and that classical conditioning is a basic form of learning that applies to all species.

7-6 What have been some applications of Pavlov's work to human health and well-being? How did Watson apply Pavlov's principles to learned fears?

Classical conditioning techniques are used to improve human health and well-being in many areas, including behavioral therapy for some types of psychological disorders. The body's immune system may also respond to classical conditioning. Pavlov's work also provided a basis for Watson's idea that human emotions and behaviors, though biologically influenced, are mainly a bundle of conditioned responses. Watson applied classical conditioning principles in his studies of "Little Albert" to demonstrate how specific fears might be conditioned.

Operant Conditioning

7-7 What is operant conditioning?

Operant conditioning is a type of learning in which behavior is strengthened if followed by a reinforcer or diminished if followed by a punisher.

7-8 Who was Skinner, and how is operant behavior reinforced and shaped?

B. F. Skinner was a college English major and aspiring writer who later entered psychology graduate school. He became modern behaviorism's most influential and controversial figure. Expanding on Edward Thorndike's *law of effect*, Skinner and others found that the behavior of rats or pigeons placed in an *operant chamber* (Skinner box) can be *shaped* by using reinforcers to guide successive approximations of the desired behavior.

7-9 How do positive and negative reinforcement differ, and what are the

basic types of reinforcers?

Reinforcement is any consequence that strengthens behavior. *Positive reinforcement* adds a desirable stimulus to increase the frequency of a behavior. *Negative reinforcement* reduces or removes an aversive stimulus to increase the frequency of a behavior.

Primary reinforcers (such as receiving food when hungry or having nausea end during an illness) are innately satisfying—no learning is required. *Conditioned* (or secondary) *reinforcers* (such as cash) are satisfying because we have learned to associate them with more basic rewards (such as the food or medicine we buy with them). Immediate reinforcers (such as a purchased treat) offer immediate payback; delayed reinforcers (such as a paycheck) require the ability to delay gratification.

7-10 How do different reinforcement schedules affect behavior?

A *reinforcement schedule* defines how often a response will be reinforced. In *continuous reinforcement* (reinforcing desired responses every time they occur), learning is rapid, but so is extinction if rewards cease. In *partial (intermittent) reinforcement* (reinforcing responses only sometimes), initial learning is slower, but the behavior is much more resistant to extinction. *Fixed-ratio schedules* reinforce behaviors after a set number of responses; *variable-ratio schedules*, after an unpredictable number. *Fixed-interval schedules* reinforce behaviors after set time periods; *variable-interval schedules*, after unpredictable time periods.

7-11 How does punishment differ from negative reinforcement, and how does punishment affect behavior?

Punishment administers an undesirable consequence (such as spanking) or withdraws something desirable (such as taking away a favorite toy) to decrease the frequency of a behavior (a child's disobedience). Negative reinforcement (taking an aspirin) removes an aversive stimulus (a headache). This desired consequence (freedom from pain) increases the likelihood that the behavior (taking aspirin to end pain) will be repeated. Punishment can have undesirable side effects, such as suppressing rather than changing unwanted behaviors; encouraging discrimination (so that the undesirable behavior appears when the punisher is not present); creating fear; teaching aggression; and fostering depression and feelings of helplessness.

7-12 Why did Skinner's ideas provoke controversy, and how might his operant conditioning principles be applied at school, in sports, at work, in parenting, and for self-improvement?

Critics of Skinner's principles believed the approach dehumanized people by neglecting their personal freedom and seeking to control their actions. Skinner replied that people's actions are already controlled by external consequences, and that reinforcement is more humane than punishment as a means for controlling behavior. Teachers can use shaping techniques to guide students' behaviors, and use interactive media such as online adaptive quizzing to provide immediate feedback. (The LearningCurve system available with this text provides such feedback, and allows students to direct the pace of their own

learning.) Coaches can build players' skills and self-confidence by rewarding small improvements. Managers can boost productivity and morale by rewarding well-defined and achievable behaviors. Parents can reward desired behaviors but not undesirable ones. We can shape our own behaviors by stating realistic goals, planning how to work toward those goals, monitoring the frequency of desired behaviors, reinforcing desired behaviors, and gradually reducing rewards as behaviors become habitual.

7-13 How does operant conditioning differ from classical conditioning?

In operant conditioning, an organism learns associations between its own behavior and resulting events; this form of conditioning involves operant behavior (behavior that operates on the environment, producing rewarding or punishing consequences). In classical conditioning, the organism forms associations between stimuli—events it does not control; this form of conditioning involves respondent behavior (automatic responses to some stimulus).

Biology, Cognition, and Learning

7-14 How do biological constraints affect classical and operant conditioning?

An animal's capacity for conditioning is limited by biological constraints, so some associations are easier to learn. Each species learns behaviors that aid its survival—a phenomenon called *preparedness*. Those who readily learned taste aversions were unlikely to eat the same toxic food again and were more likely to survive and leave descendants. Nature constrains each species' capacity for both classical conditioning and operant conditioning. Our preparedness to associate a CS with a US that follows predictably and immediately is often (but not always) adaptive. During operant training, animals may display *instinctive drift* by reverting to biologically predisposed patterns.

7-15 How do cognitive processes affect classical and operant conditioning?

In classical conditioning, animals may learn when to expect a US and may be aware of the link between stimuli and responses. In operant conditioning, *cognitive mapping* and *latent learning* research demonstrate the importance of cognitive processes in learning. Other research shows that excessive rewards (driving *extrinsic motivation*) can undermine *intrinsic motivation*.

7-16 How does observational learning differ from associative learning? How may observational learning be enabled by neural mirroring?

Observational learning involves learning by watching and imitating, rather than learning associations between different events. We learn to anticipate a behavior's consequences because we experience vicarious reinforcement or vicarious punishment. Our brain's

frontal lobes have a demonstrated ability to mirror the activity of another's brain, which some psychologists believe is enabled by *mirror neurons*; others argue it may be more due to the brain's distributed brain networks.

7-17 What is the impact of prosocial modeling and of antisocial modeling?

Children tend to imitate what a model does and says, whether the behavior being *modeled* is *prosocial* (positive, constructive, and helpful) or antisocial. If a model's actions and words are inconsistent, children may imitate the hypocrisy they observe.

7-18 What is the violence-viewing effect?

Media violence can contribute to aggression. This violence-viewing effect may be prompted by imitation and desensitization. Correlation does not equal causation, but study participants have reacted more cruelly when they have viewed violence (instead of entertaining nonviolence).

CHAPTER 8

MEMORY

Studying and Encoding Memories

8-1 What is *memory*, and how is it measured?

Memory is learning that has persisted over time, through the encoding, storage, and retrieval of information. Evidence of memory may be seen in an ability to *recall* information, *recognize* it, or *relearn* it more easily on a later attempt.

8-2 How do psychologists describe the human memory system?

Psychologists use memory models to think and communicate about memory. Information-processing models involve three processes: *encoding*, *storage*, and *retrieval*. Our agile brain processes many things simultaneously by means of *parallel processing*. The connectionism information-processing model focuses on this multitrack processing, viewing memories as products of interconnected neural networks. The three processing stages in the Atkinson-Shiffrin model are *sensory memory*, *short-term memory*, and *long-term memory*. This model has since been updated to include two important concepts: (1) *working memory*, to stress the active processing occurring in the second memory stage; and (2) automatic processing, to address the processing of information outside of conscious awareness.

8-3 How do explicit and implicit memories differ?

The human brain processes information on dual tracks, consciously and unconsciously. *Explicit* (declarative) *memories*—our conscious memories of facts and experiences—form through *effortful processing*, which requires conscious effort and attention. *Implicit* (nondeclarative) *memories*—of skills and classically conditioned associations—happen without our awareness, through *automatic processing*.

8-4 What information do we process automatically?

In addition to skills and classically conditioned associations, we automatically process incidental information about space, time, and frequency.

8-5 How does sensory memory work?

Sensory memory feeds some information into working memory for active processing there. An *iconic memory* is a very brief (a few tenths of a second) sensory memory of visual stimuli; an *echoic memory* is a three- or four-second sensory memory of auditory stimuli.

8-6 What is our short-term memory capacity?

Short-term memory capacity is about seven items, plus or minus two, but this information disappears from memory quickly without rehearsal. Our working memory capacity for active processing varies, depending on age, intelligence level, and other factors.

8-7 What are some effortful processing strategies that can help us remember new information?

Effective effortful processing strategies include *chunking*, *mnemonics*, hierarchies, and distributed practice sessions (the *spacing effect*). The *testing effect* is the finding that consciously retrieving, rather than simply rereading, information enhances memory.

8-8 What are the levels of processing, and how do they affect encoding?

Depth of processing affects long-term retention. In *shallow processing*, we encode words based on their structure or appearance. Retention is best when we use *deep processing*, encoding words based on their meaning. We also more easily remember material that is personally meaningful—the self-reference effect.

Storing and Retrieving Memories

8-9 What is the capacity of long-term memory? Are our long-term memories processed and stored in specific locations?

Our long-term memory capacity is essentially unlimited. Memories are not stored intact in the brain in single spots. Many parts of the brain interact as we encode, store, and retrieve memories.

8-10 What roles do the frontal lobes and hippocampus play in memory processing?

The frontal lobes and *hippocampus* are parts of the brain network dedicated to explicit memory formation. Many brain regions send information to the frontal lobes for processing. The hippocampus, with the help of surrounding areas of cortex, registers and temporarily holds elements of explicit memories (which are either *semantic* or *episodic*) before moving them to other brain regions for long-term storage. The neural storage of long-term memories is called *memory consolidation*.

8-11 What roles do the cerebellum and basal ganglia play in memory processing?

The cerebellum and basal ganglia are parts of the brain network dedicated to implicit memory formation. The cerebellum is important for storing classically conditioned memories. The basal ganglia are involved in motor movement and help form procedural memories for skills. Many reactions and skills learned during our first four years continue into our adult lives, though we cannot consciously remember learning these

associations and skills (infantile amnesia).

8-12 How do emotions affect our memory processing?

Emotional arousal causes an outpouring of stress hormones, which leads to activity in the brain's memory-forming areas. Significantly stressful events can trigger very clear *flashbulb memories*.

8-13 How do changes at the synapse level affect our memory processing?

Long-term potentiation (LTP) is the neural basis of learning. In LTP, neurons become more efficient at releasing and sensing the presence of neurotransmitters, and more connections develop between neurons.

8-14 How do external cues, internal emotions, and order of appearance influence memory retrieval?

External cues activate associations that help us retrieve memories; this process may occur without our awareness, as it does in *priming*. The *encoding specificity principle* is the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. Returning to the same physical context or emotional state (*mood congruency*) in which we formed a memory can help us retrieve it. The *serial position effect* accounts for our tendency to recall best the last items (which may still be in working memory) and the first items (which we've spent more time rehearsing) in a list.

Forgetting, Memory Construction, and Improving Memory

8-15 Why do we forget?

Anterograde amnesia is an inability to form new memories. *Retrograde amnesia* is an inability to retrieve old memories. Normal forgetting can happen because we have never encoded information (encoding failure); because the physical trace has decayed (storage decay); or because we cannot retrieve what we have encoded and stored (retrieval failure). Retrieval problems may result from *proactive* (forward-acting) *interference*, as prior learning interferes with recall of new information, or from *retroactive* (backward-acting) *interference*, as new learning disrupts recall of old information. Motivated forgetting occurs, but researchers have found little evidence of *repression*.

8-16 How do misinformation, imagination, and source amnesia influence our memory construction? How do we decide whether a memory is real or false?

Memories can be continually revised when retrieved, a process memory researchers call *reconsolidation*. In experiments demonstrating the *misinformation effect*, people have

formed false memories, incorporating misleading details, after receiving wrong information after an event, or after repeatedly imagining and rehearsing something that never happened. When we reassemble a memory during retrieval, we may attribute it to the wrong source (*source amnesia*). Source amnesia may help explain *déjà vu*. False memories feel like real memories and can be persistent but are usually limited to the gist of the event.

8-17 Why have reports of repressed and recovered memories been so hotly debated?

The debate focuses on whether memories of early childhood abuse are repressed and can be recovered during therapy. Incest and abuse happen more than was once supposed. But unless the victim was a child too young to remember, such traumas are usually remembered vividly, not repressed. Psychologists agree that sexual abuse happens; injustice happens; forgetting happens; recovered memories are common; memories of events that happened before age 4 are unreliable; memories “recovered” under hypnosis are especially unreliable; and memories, whether real or false, can be emotionally upsetting.

8-18 How reliable are young children’s eyewitness descriptions?

Children’s eyewitness descriptions are subject to the same memory influences that distort adult reports. If questioned soon after an event in neutral words they understand, children can accurately recall events and people involved in them.

8-19 How can you use memory research findings to do better in this and other courses?

Memory research findings suggest the following strategies for improving memory: Study repeatedly, make the material meaningful, activate retrieval cues, use mnemonic devices, minimize proactive and retroactive interference, sleep more, and test yourself to be sure you can retrieve, as well as recognize, material.

CHAPTER 9

THINKING AND LANGUAGE

Thinking

9-1 What is *cognition*, and what are the functions of concepts?

Cognition refers to all the mental activities associated with thinking, knowing, remembering, and communicating. We use *concepts*, mental groupings of similar objects, events, ideas, or people, to simplify and order the world around us. We form most concepts around *prototypes*, or best examples of a category.

9-2 What cognitive strategies assist our problem solving, and what obstacles hinder it?

An *algorithm* is a methodical, logical rule or procedure (such as a step-by-step description for evacuating a building during a fire) that guarantees a solution to a problem. A *heuristic* is a simpler strategy (such as running for an exit if you smell smoke) that is usually speedier than an algorithm but is also more error prone. *Insight* is not a strategy-based solution, but rather a sudden flash of inspiration that solves a problem. Obstacles to problem solving include *confirmation bias*, which predisposes us to verify rather than challenge our hypotheses, and *fixation*, such as *mental set*, which may prevent us from taking the fresh perspective that would lead to a solution.

9-3 What is *intuition*, and how can the availability and representative heuristics influence our decisions and judgments?

Intuition is the effortless, immediate, automatic feelings or thoughts we often use instead of systematic reasoning. Heuristics, such as the *representativeness heuristic*, enable snap judgments. Using the *availability heuristic*, we judge the likelihood of things based on how readily they come to mind.

9-4 What factors exaggerate our fear of unlikely events?

We tend to be afraid of what our ancestral history has prepared us to fear, what we cannot control, what is immediate, and what is most readily available. We fear too little the ongoing threats that claim lives one by one, such as traffic accidents and diseases.

9-5 How are our decisions and judgments affected by overconfidence, belief perseverance, and framing?

Overconfidence can lead us to overestimate the accuracy of our beliefs. When a belief we have formed and explained has been discredited, *belief perseverance* may cause us to cling to that belief. A remedy for belief perseverance is to consider how we might have

explained an opposite result. *Framing* is the way a question or statement is presented. Subtle differences in presentation can dramatically alter our responses.

9-6 How do smart thinkers use intuition?

Smart thinkers welcome their intuitions (which are usually adaptive), but also know when to override them. When making complex decisions we may benefit from gathering as much information as possible and then taking time to let our two-track mind process it.

9-7 What is *creativity*, and what fosters it?

Creativity, the ability to produce novel and valuable ideas, correlates somewhat with aptitude, but is more than school smarts. Aptitude tests require *convergent thinking*, but creativity requires *divergent thinking*. Robert Sternberg has proposed that creativity involves expertise; imaginative thinking skills; a venturesome personality; intrinsic motivation; and a creative environment that sparks, supports, and refines creative ideas.

9-8 What do we know about thinking in other species?

Researchers make inferences about other species' consciousness and intelligence based on behavior. Evidence from studies of various species shows that many other animals use concepts, numbers, and tools and that they transmit learning from one generation to the next (cultural transmission). And, like humans, some other species show insight, self-awareness, altruism, cooperation, and grief.

Language and Thought

9-9 What are the structural components of a language?

Phonemes are a language's basic units of sound. *Morphemes* are the elementary units of meaning. *Grammar*—the system of rules that enables us to communicate—includes semantics (rules for deriving meaning) and syntax (rules for ordering words into sentences).

9-10 How do we acquire language, and what is *universal grammar*?

As our biology and experience interact, we readily learn the specific grammar and vocabulary of the language we experience as children. Linguist Noam Chomsky has proposed that all human languages share a universal grammar—the basic building blocks of language—and that humans are born with a predisposition to learn language. Human languages share some commonalities, but other researchers note that children learn grammar as they discern language patterns.

9-11 What are the milestones in language development, and when is the critical period for acquiring language?

Language development's timing varies, but all children follow the same sequence.

Receptive language (the ability to understand what is said to or about you) develops before productive language (the ability to produce words). At about 4 months of age, infants *babble*, making sounds found in languages from all over the world, which by about 10 months includes only the sounds found in their household language. Around 12 months of age, children begin to speak in single words. This *one-word stage* evolves into *two-word (telegraphic)* utterances before their second birthday, after which they begin speaking in full sentences. Childhood is a critical period for learning language. A delay in exposure until age 2 or 3 produces a rush of language. But children not exposed to either a spoken or a signed language until age 7 will never master any language. The importance of early language experiences is often evident in deaf children born to hearing-nonsigning parents.

9-12 What brain areas are involved in language processing and speech?

Aphasia is an impairment of language, usually caused by left-hemisphere damage. Two important language- and speech-processing areas are *Broca's area*, a region of the left frontal lobe that controls language expression, and *Wernicke's area*, a region in the left temporal lobe that controls language reception. Language processing is spread across other brain areas as well, with different neural networks handling specific linguistic subtasks.

9-13 What do we know about other species' capacity for language?

Many chimpanzees and bonobos have learned to communicate with humans by signing or by pushing buttons, developed vocabularies of nearly 400 words, communicated by stringing these words together, taught their skills to younger animals, and demonstrated some understanding of syntax. While only humans communicate in complex sentences, other animals' impressive abilities to think and communicate challenge humans to consider what this means about the moral rights of other species.

9-14 What is the relationship between thinking and language, and what is the value of thinking in images?

Although Benjamin Lee Whorf's *linguistic determinism* hypothesis suggested that language determines thought, it is more accurate to say that language influences thought (linguistic relativism). Different languages embody different ways of thinking, and immersion in bilingual education can enhance thinking. We often think in images when we use implicit (nondeclarative, procedural) memory—our automatic memory system for motor and cognitive skills and classically conditioned associations. Thinking in images can increase our skills when we mentally practice upcoming events. Process simulation (focusing on the steps needed to reach a goal) is effective, but outcome simulation (fantasizing about having achieved the goal) does little.

CHAPTER 10

INTELLIGENCE

What Is Intelligence?

10-1 How do psychologists define *intelligence*, and what are the arguments for *g*?

Intelligence is the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. Charles Spearman proposed that we have one *general intelligence (g)* underlying all mental abilities. Through his work with factor analysis, a statistical procedure that identifies clusters of related abilities, he noted that those who score high in one area typically score higher than average in other areas. L. L. Thurstone disagreed and identified seven different clusters of mental abilities. Yet a tendency remained for high scorers in one cluster to score high in other clusters, providing further evidence of a *g* factor.

10-2 How do Gardner's and Sternberg's theories of multiple intelligences differ, and what criticisms have they faced?

Howard Gardner proposed eight independent intelligences (linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, and naturalist), as well as a possible ninth (existential intelligence). The different intelligences of people with *savant syndrome*, autism spectrum disorder (ASD), and certain kinds of brain damage seem to support his view. Robert Sternberg's triarchic theory proposes three intelligence areas that predict real-world skills: analytical (academic problem solving), creative (trailblazing smarts), and practical (street smarts). Critics note research that has confirmed a general intelligence factor, which widely predicts performance. But highly successful people also tend to be conscientious, well-connected, and doggedly energetic, with both ability *and* motivation counting.

10-3 What are the four components of emotional intelligence?

Emotional intelligence, which is an aspect of social intelligence, includes the abilities to perceive, understand, manage, and use emotions. Emotionally intelligent people tend to be happy, healthy, and more successful personally and professionally. Some critics question whether calling these abilities “intelligence” stretches that concept too far.

Assessing Intelligence

10-4 What is an intelligence test, and how do achievement and aptitude tests differ?

An *intelligence test* assesses an individual's mental aptitudes and compares them with those of others, using numerical scores. *Aptitude tests* measure the ability to learn, while *achievement tests* measure what we have already learned.

10-5 When and why were intelligence tests created, and how do today's tests differ from early intelligence tests?

Francis Galton, who was fascinated with measuring what he believed to be hereditary genius (to encourage those with exceptional abilities to reproduce), attempted but failed to construct a simple intelligence test in the late 1800s. Alfred Binet, who tended toward an environmental explanation of intelligence differences, started the modern intelligence-testing movement in France in the early 1900s, when he developed questions to help predict children's future progress in the Paris school system. Binet hoped his test would improve children's education but feared it might be used to label them. During the early twentieth century, Lewis Terman of Stanford University revised Binet's work for use in the United States. Terman thought his *Stanford-Binet* could help guide people toward appropriate opportunities, but his belief in an intelligence that was fixed at birth and differed among ethnic groups realized Binet's fear that intelligence tests would be used to limit children's opportunities. William Stern contributed the concept of the *IQ* (intelligence quotient). The most widely used intelligence tests today are the *Wechsler Adult Intelligence Scale (WAIS)* and Wechsler's tests for children. These tests differ from their predecessors in the way they offer an overall intelligence score as well as scores for verbal comprehension, perceptual organization, working memory, and processing speed.

10-6 What is a normal curve, and what does it mean to say that a test has been standardized and is reliable and valid?

The distribution of test scores often forms a *normal* (bell-shaped) *curve* around the central average score, with fewer and fewer scores at the extremes. *Standardization* establishes a basis for meaningful score comparisons by giving a test to a representative sample of future test-takers. *Reliability* is the extent to which a test yields consistent results (on two halves of the test, on alternative forms of the test, or upon retesting). *Validity* is the extent to which a test measures or predicts what it is supposed to. A test has *content validity* if it samples the pertinent behavior (as a driving test measures driving ability). It has *predictive validity* if it predicts a behavior it was designed to predict. (Aptitude tests have predictive validity if they can predict future achievements; their predictive power is best for the early school years.)

10-7 What are cross-sectional studies and longitudinal studies, and why is it important to know which method was used?

The differing intelligence findings of cross-sectional and longitudinal studies—that mental ability declines with age or that it remains stable (or even increases)—illustrate the fact that *cross-sectional studies* compare people of different eras and life circumstances. This can provide an excellent snapshot of a particular point in time, but *longitudinal studies* are superior for tracing the evolution of traits over a longer period.

10-8 How does aging affect crystallized and fluid intelligence?

Cross-sectional and longitudinal studies have shown that *fluid intelligence* declines in older adults, in part because neural processing slows. However, *crystallized intelligence* tends to increase.

10-9 How stable are intelligence test scores over the life span?

The stability of intelligence test scores increases with age. At age 4, scores fluctuate somewhat but begin to predict adolescent and adult scores. By early adolescence, scores are very stable and predictive.

10-10 What are the traits of those at the low and high intelligence extremes?

An intelligence test score of or below 70 is one diagnostic criterion for the diagnosis of *intellectual disability*; other criteria are limited conceptual, social, and practical skills. People at the high intelligence extreme tend to be healthy and well-adjusted, as well as unusually successful academically.

Genetic and Environmental Influences on Intelligence

10-11 What evidence points to a genetic influence on intelligence, and what is *heritability*?

Studies of twins, family members, and adoptive parents and siblings indicate a significant hereditary contribution to intelligence scores. Intelligence is polygenetic. *Heritability* is the proportion of variation among individuals in a group that can be attributed to genes.

10-12 What does evidence reveal about environmental influences on intelligence?

Studies of children raised in impoverished environments with minimal social interaction indicate that life experiences significantly influence intelligence test performance. No evidence supports the idea that normal, healthy children can be molded into geniuses by

growing up in an exceptionally enriched environment.

10-13 How and why do the genders differ in mental ability scores?

Males and females have the same average intelligence test scores, but they tend to differ in some specific abilities. Girls are better spellers, more verbally fluent, better at locating objects, better at detecting emotions, and more sensitive to touch, taste, and color. Boys outperform girls at spatial ability and related mathematics, though boys and girls hardly differ in math computation and overall math performance. Boys also outnumber girls at the low and high extremes of mental abilities. Evolutionary and cultural explanations have been proposed for these gender differences.

10-14 How and why do racial and ethnic groups differ in mental ability scores?

Racial and ethnic groups differ in their average intelligence test scores. The evidence suggests that environmental differences are responsible for these group differences.

10-15 Are intelligence tests inappropriately biased? How does stereotype threat affect test-takers' performance?

Aptitude tests aim to predict how well a test-taker will perform in a given situation. So they are necessarily “biased” in the sense that they are sensitive to performance differences caused by cultural experience. By “inappropriately biased,” psychologists mean that a test predicts less accurately for one group than for another. In this sense, most experts consider the major aptitude tests unbiased. *Stereotype threat*, a self-confirming concern that one will be evaluated based on a negative stereotype, affects performance on all kinds of tests.

CHAPTER 11

WHAT DRIVES US: HUNGER, SEX, BELONGING, AND ACHIEVEMENT

Basic Motivational Concepts

11-1 How do psychologists define *motivation*? From what perspectives do they view motivated behavior?

Motivation is a need or desire that energizes and directs behavior. The *instinct/evolutionary* perspective explores genetic influences on complex behaviors. *Drive-reduction theory* explores how *physiological needs* create aroused tension states (drives) that direct us to satisfy those needs. Environmental *incentives* can intensify drives. Drive-reduction's goal is *homeostasis*, maintaining a steady internal state. Arousal theory proposes that some behaviors (such as those driven by curiosity) do not reduce physiological needs but rather are prompted by a search for an optimum level of arousal. The *Yerkes-Dodson law* describes the relationship between arousal and performance. Abraham Maslow's *hierarchy of needs* proposes a pyramid of human needs, from basic needs up to higher-level needs.

Hunger

11-2 What physiological factors produce hunger?

Hunger pangs correspond to stomach contractions, but hunger also has other causes. Neural areas in the brain, some within the hypothalamus, monitor blood chemistry (including level of *glucose*) and incoming information about the body's state. Appetite hormones include ghrelin (secreted by an empty stomach); insulin (controls blood glucose); leptin (secreted by fat cells); orexin (secreted by the hypothalamus); and PYY (secreted by the digestive tract). *Basal metabolic rate* is the body's resting rate of energy expenditure. The body may have a *set point* (a biologically fixed tendency to maintain an optimum weight) or a looser settling point (also influenced by the environment).

11-3 What cultural and situational factors influence hunger?

Hunger also reflects our memory of when we last ate and our expectation of when we should eat again. Humans as a species prefer certain tastes (such as sweet and salty), but our individual preferences are also influenced by conditioning, culture, and situation.

Some taste preferences have survival value.

11-4 How does obesity affect physical and psychological health, and what factors are involved in weight management?

Obesity, defined by a body mass index (BMI) of 30 or above, is associated with increased depression (especially among women), bullying, and many physical health risks. Genes and environment interact to produce obesity. Storing fat was adaptive to our ancestors, and fat requires less food intake to maintain than it did to gain. Set point and metabolism matter; lean people tend to move around more. Twin and adoption studies indicate that body weight is also genetically influenced. Environmental influences include sleep loss, social influence, and food and activity levels. Those wishing to lose weight are advised to make a lifelong change in habits: Begin only if you feel motivated and self-disciplined; exercise and get enough sleep; minimize exposure to tempting food cues; limit variety and eat healthy foods; reduce portion sizes; space meals throughout the day; beware the binge; plan ahead to control eating during social events; forgive the occasional lapse; publicly chart your progress; and connect to a support group.

Sexual Motivation

11-5 How do hormones influence human sexual motivation?

For all but those few of us considered *asexual*, dating and mating become a high priority from puberty on. The female *estrogen* and male *testosterone* hormones influence human sexual behavior less directly than they influence sexual behavior in other species. Women's sexuality is more responsive to testosterone level than to estrogen level. Short-term shifts in testosterone level are normal in men, partly in response to stimulation.

11-6 What is the human sexual response cycle, and how do sexual dysfunctions and paraphilias differ?

William Masters and Virginia Johnson described four stages in the human *sexual response cycle*: excitement, plateau, orgasm, and resolution. During resolution there is a *refractory period* in which renewed arousal and orgasm are impossible. *Sexual dysfunctions* are problems that consistently impair sexual arousal or functioning. They include *erectile disorder* and *female orgasmic disorder*, and can often be successfully treated by behaviorally oriented therapy or drug therapy. *Paraphilias* are considered disordered if a person experiences distress from an unusual sexual interest or if it entails harm or risk of harm to others.

11-7 How can sexually transmitted infections be prevented?

Safe-sex practices help prevent sexually transmitted infections (STIs). Condoms are especially effective in preventing transmission of HIV, the virus that causes *AIDS*. A vaccination administered before sexual contact can prevent most human papilloma virus

infections.

11-8 How do external and imagined stimuli contribute to sexual arousal?

External stimuli can trigger sexual arousal in both men and women. Sexually explicit material may lead people to perceive their partners as comparatively less appealing and to devalue their relationships. Viewing sexually coercive material can lead to increased acceptance of violence toward women. Extensive online pornography exposure may desensitize young men to normal sexuality, leading to erectile problems and lowered sexual desire in real life. Imagined stimuli (dreams and fantasies) also influence sexual arousal.

11-9 What factors influence teenagers' sexual behaviors and use of contraceptives?

Teen sexuality varies from culture to culture and era to era. Factors contributing to these variations include communication about birth control; impulsivity; alcohol use; and mass media. High intelligence, religious engagement, father presence, and service learning participation predict teen sexual restraint.

11-10 What has research taught us about sexual orientation?

Sexual orientation is an enduring sexual attraction toward members of one's own sex, the other sex, or both sexes. About 3 or 4 percent of men and 2 percent of women in Europe and the United States identify as exclusively homosexual. Men tend to respond more to sexual depictions involving their preferred sex (for heterosexuals, images of women); women tend to respond more nonspecifically to images of males and females. There is no evidence that environmental influences determine sexual orientation. Evidence for biological influences includes same-sex attraction in other species; gay-straight trait and brain differences; genetic influences; and prenatal influences.

11-11 What role do social factors play in our sexuality?

Scientific research on sexual motivation does not attempt to define the personal meaning of sex in our lives, which is influenced by many social factors. Sex is a socially significant act and is an expression of our profoundly social nature. Sex at its human best is life uniting and love renewing.

Affiliation and Achievement

11-12 What evidence points to our human affiliation need—our need to belong?

Our *affiliation need*—to feel connected and identified with others—had survival value for our ancestors, which may explain why humans in every society live in groups. Social bonds help us to be healthier and happier, and feeling loved activates brain regions

associated with reward and safety systems. *Ostracism* is the deliberate exclusion of individuals or groups. Social isolation can put us at risk mentally and physically.

11-13 How does social networking influence us?

We connect with others through social networking, strengthening our relationships with those we already know. When networking, people tend toward increased self-disclosure. People with high *narcissism* are especially active on social networking sites. Working out strategies for self-control and disciplined usage can help people maintain a healthy balance between their real-world and online time.

11-14 What is achievement motivation?

Achievement motivation is a desire for significant accomplishment, for mastery of skills or ideas, for control, and for attaining a high standard. High achievement motivation leads to greater success, especially when combined with determined, persistent *grit*.

CHAPTER 12

EMOTIONS, STRESS, AND HEALTH

Introduction to Emotion

12-1 How do arousal, expressive behavior, and cognition interact in emotion?

Emotions are responses of the whole organism, involving physiological arousal, expressive behaviors, and conscious experience. Theories of emotion generally address two major questions: (1) Does physiological arousal come before or after emotional feelings? and (2) how do feeling and cognition interact? The *James-Lange theory* maintains that emotional feelings follow our body's response to emotion-inducing stimuli (we observe our heart pounding and feel fear). The *Cannon-Bard theory* proposes that our physiological response to an emotion-inducing stimulus occurs at the same time as our subjective feeling of the emotion (one does not cause the other).

12-2 To experience emotions, must we consciously interpret and label them?

The Schachter-Singer *two-factor theory* holds that our emotions have two ingredients, physical arousal and a cognitive label; the cognitive labels we put on our states of arousal are an essential ingredient of emotion. Lazarus agreed that many important emotions arise from our interpretations or inferences. But Zajonc and LeDoux have contended that some simple emotional responses occur instantly, not only outside our conscious awareness, but before any cognitive processing occurs. This interplay between emotion and cognition illustrates our two-track mind.

12-3 What is the link between emotional arousal and the autonomic nervous system?

The arousal component of emotion is regulated by the autonomic nervous system's sympathetic (arousing) and parasympathetic (calming) divisions. In a crisis, the fight-or-flight response automatically mobilizes your body for action.

12-4 Do different emotions activate different physiological and brain-pattern responses?

The large-scale body changes that accompany fear, anger, and sexual arousal are very similar (increased perspiration, breathing, and heart rate), though they feel different. Emotions may be similarly arousing, but some subtle physiological responses, such as facial muscle movements, distinguish them. More meaningful differences have been

found in activity in some brain pathways and cortical areas.

12-5 How effective are polygraphs in using body states to detect lies?

Polygraphs (lie detectors) attempt to measure several physiological indicators of emotion, but are not accurate enough to justify widespread use in business and law enforcement. The use of guilty knowledge questions and new forms of technology may produce better indications of lying.

Expressing Emotion

12-6 How do we communicate nonverbally?

Much of our communication is through body movements, facial expressions, and voice tones. Even seconds-long filmed slices of behavior can reveal feelings.

12-7 How do the genders differ in their ability to communicate nonverbally?

Women tend to read emotional cues more easily and to be more empathic. They also express more emotion.

12-8 How are gestures and facial expressions understood within and across cultures?

The meaning of gestures varies with culture, but facial expressions, such as those of happiness and sadness, are common the world over. Cultures also differ in the amount of emotion they express.

12-9 How do our facial expressions influence our feelings?

Research on the *facial feedback effect* shows that our facial expressions can trigger emotional feelings and signal our body to respond accordingly. We also mimic others' expressions, which helps us empathize. A similar *behavior feedback effect* is the tendency of behavior to influence our own and others' thoughts, feelings, and actions.

Experiencing Emotion

12-10 What are some of the basic emotions?

Carroll Izard's 10 basic emotions are joy, interest-excitement, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt.

12-11 What are the causes and consequences of anger?

Anger is most often evoked by misdeeds that we interpret as willful, unjustified, and

avoidable. But smaller frustrations and blameless annoyances can also trigger anger. Chronic hostility is a key negative emotion linked to heart disease. Emotional *catharsis* may be temporarily calming, but it does not reduce anger; expressing anger can make us angrier. Experts suggest reducing the level of physiological arousal of anger by waiting, finding a healthy distraction or support, and trying to move away from the situation mentally. Controlled assertions of feelings may resolve conflicts, and forgiveness may rid us of angry feelings.

12-12 What is the *feel-good, do-good phenomenon*, and what is the focus of positive psychology research?

Happy people tend to be healthy, energized, and satisfied with life, making them more willing to help others (the *feel-good, do-good phenomenon*). *Positive psychologists* use scientific methods to study human flourishing, aiming to discover and promote strengths and virtues that help individuals and communities to thrive.

12-13 How do time, wealth, adaptation, and comparison affect our happiness levels?

The moods triggered by good or bad events seldom last beyond that day. Even significant good events, such as sudden wealth, seldom increase happiness for long. Happiness is relative to our own experiences (the *adaptation-level phenomenon*) and to others' success (the *relative deprivation principle*).

12-14 What predicts happiness, and how can we be happier?

Some individuals, because of their genetic predispositions and personal histories, are happier than others. Cultures, which vary in the traits they value and the behaviors they expect and reward, also influence personal levels of happiness. Tips for increasing happiness levels: take charge of your schedule, act happy, seek meaningful work and leisure, buy shared experiences rather than things, exercise, sleep enough, foster friendships, focus beyond the self, and nurture gratitude and spirituality.

Stress and Illness

12-15 How does our appraisal of an event affect our stress reaction, and what are the three main types of stressors?

Stress is the process by which we appraise and respond to stressors that challenge or threaten us. If we appraise an event as challenging, we will be aroused and focused in preparation for success; if as a threat, we will experience a stress reaction, and our health may suffer. The three main types of stressors are catastrophes, significant life changes, and daily hassles and social stress.

12-16 How do we respond and adapt to stress?

Walter Cannon viewed the stress response as a fight-or-flight system. Hans Selye proposed a general three-phase (alarm, resistance, exhaustion) *general adaptation syndrome (GAS)*. Facing stress, women may have a *tend-and-befriend* response; men may withdraw socially, turn to alcohol, or become emotionally insensitive.

12-17 How does stress make us more vulnerable to disease?

Psychoneuroimmunology is the study of how psychological, neural, and endocrine processes together affect the immune system and resulting health. Stress diverts energy from the immune system, inhibiting the activities of its B and T lymphocytes, macrophages, and NK cells. Stress does not cause illness, but by altering our immune functioning it may make us more vulnerable to diseases and influence their progression.

12-18 Why are some of us more prone than others to coronary heart disease?

Coronary heart disease has been linked with the reactive, anger-prone *Type A* personality. Compared with relaxed, easygoing *Type B* personalities, who are less likely to experience heart disease, Type A people secrete more stress hormones. Chronic stress also contributes to persistent inflammation, which is associated with heart and other health problems, including depression.

12-19 So, does stress cause illness?

Stress may not directly cause illness, but it does make us more vulnerable, by influencing our behaviors and our physiology.

Health and Coping

12-20 In what two ways do people try to alleviate stress?

We use *problem-focused coping* to change the stressor or the way we interact with it. We use *emotion-focused coping* to avoid or ignore stressors and attend to emotional needs related to stress reactions.

12-21 How does a perceived lack of control affect health?

A perceived lack of control provokes an outpouring of hormones that put people's health at risk. Being unable to avoid repeated aversive events can lead to *learned helplessness*. People who perceive an *internal locus of control* achieve more, enjoy better health, and are happier than those who perceive an *external locus of control*.

12-22 Why is self-control important, and can our self-control be depleted?

Self-control requires attention and energy, but predicts good health, higher income, and better school performance; it is a better predictor than an intelligence test score of future academic and life success. Self-control varies over time. Researchers disagree about the

factors influencing self-control, but strengthening it can lead to a healthier, happier, and more successful life.

12-23 How does an optimistic outlook affect health and longevity?

Studies of people with an optimistic outlook show that their immune system is stronger, their blood pressure does not increase as sharply in response to stress, their recovery from heart bypass surgery is faster, and their life expectancy is longer, compared with their pessimistic counterparts.

12-24 How does social support promote good health?

Social support promotes health by calming us, by reducing blood pressure and stress hormones, and by fostering stronger immune functioning. We can significantly reduce our stress and increase our health by building and maintaining relationships, and by finding meaning even in difficult times.

12-25 How effective is aerobic exercise as a way to manage stress and improve well-being?

Aerobic exercise is sustained, oxygen-consuming activity that increases heart and lung fitness. It increases arousal, leads to muscle relaxation and sounder sleep, triggers the production of neurotransmitters, and enhances self-image. It can relieve depression and, in later life, is associated with better cognitive functioning and longer life.

12-26 In what ways might relaxation and meditation influence stress and health?

Relaxation and meditation have been shown to reduce stress by relaxing muscles, lowering blood pressure, improving immune functioning, and lessening anxiety and depression. *Mindfulness meditation* is a reflective practice of attending to current experiences in a nonjudgmental and accepting manner. Massage therapy also relaxes muscles and reduces depression.

12-27 What is the faith factor, and what are some possible explanations for the link between faith and health?

The faith factor is the finding that religiously active people tend to live longer than those who are not religiously active. Possible explanations may include intervening variables such as the healthy behaviors, social support, or positive emotions often found among people who regularly attend religious services.

CHAPTER 13

SOCIAL PSYCHOLOGY

Social Thinking

13-1 What do social psychologists study? How do we tend to explain others' behavior and our own?

Social psychologists use scientific methods to study how people think about, influence, and relate to one another. They study the social influences that explain why the same person will act differently in different situations. When explaining others' behavior, we may—especially if we come from an individualist Western culture—commit the *fundamental attribution error*, by underestimating the influence of the situation and overestimating the effects of stable, enduring traits. When explaining our own behavior, we more readily attribute it to the influence of the situation.

13-2 How do attitudes and actions interact?

Peripheral route persuasion uses incidental cues (such as celebrity endorsement) to try to produce fast but relatively thoughtless changes in attitudes. *Central route persuasion* offers evidence and arguments to trigger thoughtful responses. When other influences are minimal, attitudes that are stable, specific, and easily recalled can affect our actions. Actions can modify attitudes, as in the *foot-in-the-door phenomenon* and *role playing*. When our attitudes don't fit with our actions, *cognitive dissonance theory* suggests that we will reduce tension by changing our attitudes to match our actions.

Social Influence

13-3 What is *social contagion*, and how do conformity experiments reveal the power of social influence?

Social contagion (the chameleon effect)—our tendency to unconsciously imitate others' behavior, expressions, postures, inflections, and moods—is a form of *conformity*. Social networks serve as contagious pathways for moods, both good and bad. Solomon Asch and others have found that we are most likely to adjust our behavior or thinking to coincide with a group standard when we feel incompetent or insecure, our group has at least three people, everyone else agrees, we admire the group's status and attractiveness, we have not already committed to another response, we know we are being observed, and our culture encourages respect for social standards. We may conform to gain

approval (*normative social influence*) or because we are willing to accept others' opinions as new information (*informational social influence*).

13-4 What did Milgram's obedience experiments teach us about the power of social influence?

Stanley Milgram's experiments—in which people obeyed orders even when they thought they were harming another person—demonstrated that strong social influences can make ordinary people conform to falsehoods or give in to cruelty. Obedience was highest when the person giving orders was nearby and was perceived as a legitimate authority figure, the research was supported by a prestigious institution, the victim was depersonalized or at a distance, and there were no role models for defiance.

13-5 What do the social influence studies teach us about ourselves? How much power do we have as individuals?

These experiments have demonstrated that strong social influences can make people conform to falsehoods or capitulate to cruelty. The power of the individual (personal control) and the power of the situation (social control) interact. A small minority that consistently expresses its views may sway the majority, as may even a single committed individual.

13-6 How does the presence of others influence our actions, via social facilitation, social loafing, and deindividuation?

In *social facilitation*, the mere presence of others arouses us, improving our performance on easy or well-learned tasks but decreasing it on difficult ones. In *social loafing*, group work makes us feel less responsible, and we may free ride on others' efforts. When the presence of others both arouses us and makes us feel anonymous, we may experience *deindividuation*—loss of self-awareness and self-restraint.

13-7 How can group interaction enable group polarization?

In *group polarization*, group discussions with like-minded others strengthen members' prevailing beliefs and attitudes.

13-8 What role does the Internet play in group polarization?

Internet communication magnifies the effect of connecting like-minded people, for better and for worse. People find support, which strengthens their ideas, but also often isolation from those with different opinions. Separation plus conversation may thus lead to group polarization.

13-9 How can group interaction enable groupthink?

Groupthink is driven by a desire for harmony within a decision-making group, overriding realistic appraisal of alternatives. Group leaders can harness the benefits of group interaction by assigning people to identify possible problems, and by welcoming various opinions and expert critique.

Antisocial Relations

13-10 What is *prejudice*? How do explicit and implicit prejudice differ?

Prejudice is an unjustifiable, usually negative, attitude toward a group and its members. Prejudice's three components are beliefs (often *stereotypes*), emotions, and predispositions to action (*discrimination*). Explicit (overt) prejudice in North America has decreased over time, but implicit prejudice—an unthinking knee-jerk response operating below conscious awareness—continues.

13-11 What groups are frequent targets of prejudice?

Prejudice involves both explicit and implicit negative attitudes toward people of a particular racial or ethnic group, gender, sexual orientation, or belief system.

13-12 What are some social, emotional and cognitive roots of prejudice, and what are some ways to eliminate prejudice?

The social roots of prejudice include social inequalities and divisions. Higher-status groups often justify their privileged position with the *just-world phenomenon*. We tend to favor our own group (*ingroup bias*) as we divide ourselves into “us” (the *ingroup*) and “them” (the *outgroup*). Prejudice can also be a tool for protecting our emotional well-being, as when we focus our anger by blaming events on a *scapegoat*. The cognitive roots of prejudice grow from our natural ways of processing information: forming categories, remembering vivid cases, and believing that the world is just (and that our own and our group's ways of doing things are the right ways). Monitoring our feelings and actions, as well as developing new friendships, can help us free ourselves from prejudice.

13-13 How does psychology's definition of *aggression* differ from everyday usage? What biological factors make us more prone to hurt one another?

In psychology's more specific meaning, *aggression* is any act intended to harm someone physically or emotionally. Biology influences our threshold for aggressive behaviors at three levels: genetic (inherited traits), neural (activity in key brain areas), and biochemical (such as alcohol or excess testosterone in the bloodstream). Aggression is a complex behavior resulting from the interaction of biology and experience.

13-14 What psychological and social-cultural factors may trigger aggressive behavior?

Frustration (the *frustration-aggression principle*), previous reinforcement for aggressive behavior, observing aggressive role models, and poor self-control all contribute to aggression. Media violence provides *social scripts* that children learn to follow. Viewing sexual violence contributes to greater aggression toward women. Playing violent video games increases aggressive thoughts, emotions, and behaviors.

Prosocial Relations

13-15 Why do we befriend or fall in love with some people but not others?

Proximity (geographical nearness) increases liking, in part because of the *mere exposure effect*—exposure to novel stimuli increases liking of those stimuli. Physical attractiveness increases social opportunities and improves the way we are perceived. Similarity of attitudes and interests greatly increases liking, especially as relationships develop. We also like those who like us.

13-16 How does romantic love typically change as time passes?

Intimate love relationships start with *passionate love*—an intensely aroused state. Over time, the strong affection of *companionate love* may develop, especially if enhanced by an *equitable* relationship, intimate *self-disclosure*, and positive support.

13-17 What is *altruism*? When are people most—and least—likely to help?

Altruism is unselfish regard for the well-being of others. We are most likely to help when we notice an incident, interpret it as an emergency, and assume responsibility for helping. Other factors, including our mood and our similarity to the victim, also affect our willingness to help. We are least likely to help if other bystanders are present (the *bystander effect*).

13-18 How do social exchange theory and social norms explain helping behavior?

Social exchange theory is the view that we help others because it is in our own self-interest; in this view, the goal of social behavior is maximizing personal benefits and minimizing costs. Others believe that helping results from socialization, in which we are taught guidelines for expected behaviors in social situations, such as the *reciprocity norm* and the *social-responsibility norm*.

13-19 How do social traps and mirror-image perceptions fuel social conflict?

Social traps are situations in which people in conflict pursue their own individual self-interest, harming the collective well-being. Individuals and cultures in conflict also tend to form *mirror-image perceptions*: Each party views the opponent as untrustworthy and evil-intentioned, and itself as an ethical, peaceful victim. Perceptions can become *self-fulfilling prophecies*.

13-20 What can we do to promote peace?

Peace can result when individuals or groups work together to achieve *superordinate* (shared) *goals*. Research indicates that contact, cooperation, communication, and

conciliation help promote peace.

CHAPTER 14

PERSONALITY

Introduction to Personality and Psychodynamic Theories

14-1 What is *personality*, and what theories inform our understanding of personality?

Personality is an individual's characteristic pattern of thinking, feeling, and acting. Psychoanalytic (and later psychodynamic) theory and humanistic theory have become part of our cultural legacy. They also laid the foundation for later theories, such as trait and social-cognitive theories of personality.

14-2 How did Sigmund Freud's treatment of psychological disorders lead to his view of the unconscious mind?

Psychodynamic theories view personality from the perspective that behavior is a dynamic interaction between the conscious and unconscious mind. These theories trace their origin to Sigmund Freud's theory of *psychoanalysis*. In treating patients whose disorders had no clear physical explanation, Freud concluded that these problems reflected unacceptable thoughts and feelings, hidden away in the *unconscious* mind. To explore this hidden part of a patient's mind, Freud used *free association* and dream analysis.

14-3 What was Freud's view of personality?

Freud believed that personality results from conflict arising from the interaction among the mind's three systems: the *id* (pleasure-seeking impulses), *ego* (reality-oriented executive), and *superego* (internalized set of ideals, or conscience).

14-4 What developmental stages did Freud propose?

He believed children pass through five *psychosexual stages* (oral, anal, phallic, latency, and genital). According to this view, unresolved conflicts at any stage can leave a person's pleasure-seeking impulses *fixated* (stalled) at that stage.

14-5 How did Freud think people defended themselves against anxiety?

For Freud, anxiety was the product of tensions between the demands of the *id* and *superego*. The *ego* copes by using unconscious *defense mechanisms*, such as *repression*, which he viewed as the basic mechanism underlying and enabling all the others.

14-6 Which of Freud's ideas did his followers accept or reject?

Freud's early followers, the neo-Freudians, accepted many of his ideas. They differed in placing more emphasis on the conscious mind and in stressing social motives more than sex or aggression. Most contemporary psychodynamic theorists and therapists reject Freud's emphasis on sexual motivation. They stress, with support from modern research findings, the view that much of our mental life is unconscious, and they believe that our childhood experiences influence our adult personality and attachment patterns. Many also believe that our species' shared evolutionary history shaped some universal predispositions.

14-7 What are *projective tests*, how are they used, and what are some criticisms of them?

Projective tests attempt to assess personality by showing people stimuli open to many possible interpretations and treating their answers as revelations of unconscious motives. The *Thematic Apperception Test (TAT)* and the *Rorschach inkblot test* are two such tests. The TAT provides a valid and reliable map of people's implicit motives that is consistent over time. The Rorschach has low reliability and validity, but some clinicians value it as a source of suggestive leads, an icebreaker, or a revealing interview technique.

14-8 How do contemporary psychologists view Freud's psychoanalysis?

They give Freud credit for drawing attention to the vast unconscious, to the struggle to cope with anxiety and sexuality, to the conflict between biological impulses and social restraints, and for some forms of defense mechanisms. But his concept of repression, and his view of the unconscious as a collection of repressed and unacceptable thoughts, wishes, feelings, and memories, cannot survive scientific scrutiny. Freud offered after-the-fact explanations, which are hard to test scientifically. Research does not support many of Freud's specific ideas, such as the view that development is fixed in childhood. (We now know it is lifelong.)

14-9 How has modern research developed our understanding of the unconscious?

Research confirms that we do not have full access to all that goes on in our mind, though today's science views the unconscious as a separate and parallel track of information processing that occurs outside our awareness. This processing includes schemas that control our perceptions, priming, implicit memories of learned skills, instantly activated emotions, and stereotypes that filter our information processing of others' traits and characteristics. Research also supports reaction formation and projection (the false consensus effect), and the idea that we unconsciously defend ourselves from anxiety (as seen in experiments testing *terror management theory*).

Humanistic Theories and Trait Theories

14-10 How did humanistic psychologists view personality, and what was their goal in studying personality?

The *humanistic* psychologists' view of personality focused on the potential for healthy personal growth and people's striving for self-determination and self-realization. Abraham Maslow proposed that human motivations form a *hierarchy of needs*; if basic needs are fulfilled, people will strive toward *self-actualization* and *self-transcendence*. Carl Rogers believed that the ingredients of a growth-promoting environment are acceptance (including *unconditional positive regard*), genuineness, and empathy. *Self-concept* was a central feature of personality for both Maslow and Rogers.

14-11 How did humanistic psychologists assess a person's sense of self?

Some rejected any standardized assessments and relied on interviews and conversations. Rogers sometimes used questionnaires in which people described their ideal and actual selves, which he later used to judge progress during therapy.

14-12 How have humanistic theories influenced psychology? What criticisms have they faced?

Humanistic psychology helped renew interest in the concept of self, and also laid the groundwork for today's scientific subfield of positive psychology. Critics have said that humanistic psychology's concepts are vague and subjective, its values self-centered, and its assumptions naively optimistic.

14-13 How do psychologists use traits to describe personality?

Trait theorists see personality as a stable and enduring pattern of behavior. They have been more interested in trying to describe our differences than in explaining them. Using factor analysis, they identify clusters of behavior tendencies that occur together. Genetic predispositions influence many traits.

14-14 What are some common misunderstandings about introversion?

Western cultures prize extraversion, but introverts have different, equally important skills. Introversion does not equal shyness, and extraverts don't always outperform introverts as leaders or in sales success. Introverts often experience great achievement; many introverts prosper.

14-15 What are *personality inventories*, and what are their strengths and weaknesses as trait-assessment tools?

Personality inventories (such as the *MMPI*) are questionnaires on which people respond to items designed to gauge a wide range of feelings and behaviors. Test items are *empirically derived*, and the tests are objectively scored. Objectivity does not guarantee validity; people can fake their answers to create a good impression (but may then score high on a lie scale that assesses faking).

14-16 Which traits seem to provide the most useful information about

personality variation?

The Big Five personality factors—conscientiousness, agreeableness, neuroticism, openness, and extraversion (CANOE)—currently offer our best approximation of the basic trait dimensions. These factors are quite stable and appear to be found in all cultures. Many genes, each having small effects, combine to influence our traits, and heritability generally runs about 40 percent for each dimension.

14-17 Does research support the consistency of personality traits over time and across situations?

A person's average traits persist over time and are predictable over many different situations. But traits cannot predict behavior in any one situation.

Social-Cognitive Theories and the Self

14-18 How do social-cognitive theorists view personality development, and how do they explore behavior?

Albert Bandura first proposed the *social-cognitive perspective*, which emphasizes the interaction of our traits with our situations. Social-cognitive researchers apply principles of learning, cognition, and social behavior to personality. *Reciprocal determinism* describes the interaction and mutual influence of behavior, internal cognition, and environment. Assessment situations involving simulated conditions exploit the principle that the best predictor of future behavior is a person's actions in similar situations.

14-19 What criticisms have social-cognitive theorists faced?

Social-cognitive theorists build on well-established concepts of learning and cognition, sensitizing researchers to the ways situations affect, and are affected by, individuals. They have been faulted for underemphasizing the importance of unconscious motives, emotions, and biologically influenced traits.

14-20 Why has psychology generated so much research on the self? How important is self-esteem to our well-being?

The *self* is the center of personality, organizing our thoughts, feelings, and actions. Considering possible selves helps motivate us toward positive development, but focusing too intensely on ourselves can lead to the *spotlight effect*. High *self-esteem* correlates with less pressure to conform, with persistence at difficult tasks, and with happiness. But the direction of the correlation is unclear. Rather than unrealistically promoting self-worth, it's better to reward children's achievements, thus promoting feelings of competence.

14-21 How do excessive optimism, blindness to one's own incompetence, and self-serving bias reveal the costs of self-esteem, and

how do defensive and secure self-esteem differ?

Excessive optimism can lead to complacency and prevent us from seeing real risks, while blindness to one's own incompetence may lead us to make the same mistakes repeatedly. *Self-serving bias* is our tendency to perceive ourselves favorably, as when viewing ourselves as better than average or when accepting credit for our successes but not blame for our failures. Defensive self-esteem is fragile, focuses on sustaining itself, and views failure or criticism as a threat. Secure self-esteem enables us to feel accepted for who we are.

CHAPTER 15

PSYCHOLOGICAL DISORDERS

Introduction to Psychological Disorders

15-1 How should we draw the line between normality and disorder?

According to psychologists and psychiatrists, *psychological disorders* are marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. Such dysfunctional or maladaptive thoughts, emotions, or behaviors interfere with daily life, and thus are disordered.

15-2 How do the medical model and the biopsychosocial approach influence our understanding of psychological disorders?

The *medical model* assumes that psychological disorders have physical causes that can be diagnosed, treated, and, in most cases, cured through therapy, sometimes in a hospital. The biopsychosocial perspective assumes that disordered behavior comes from the interaction of biological characteristics, psychological dynamics, and social-cultural circumstances. This approach has given rise to the vulnerability-stress model, in which individual characteristics and environmental stressors combine to increase or decrease the likelihood of developing a psychological disorder, a model supported by *epigenetics* research.

15-3 How and why do clinicians classify psychological disorders, and why do some psychologists criticize the use of diagnostic labels?

The American Psychiatric Association's DSM-5 (*Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition) contains diagnostic labels and descriptions that provide a common language and shared concepts for communication and research. Critics of the DSM say it casts too wide a net, pathologizing normal behaviors. A complementary approach to classification is the U.S. National Institute of Mental Health's Research Domain Criteria (RDoC) project, a framework that organizes disorders according to behaviors and brain activity along several dimensions. Any classification attempt produces diagnostic labels that may create preconceptions, which bias perceptions of the labeled person's past and present behavior.

15-4 Why is there controversy over attention-deficit/hyperactivity disorder?

A child (or, less commonly, an adult) who displays extreme inattention and/or hyperactivity and impulsivity may be diagnosed with *attention-deficit/hyperactivity disorder (ADHD)*. The controversy centers on whether the growing number of ADHD

cases reflects overdiagnosis or increased awareness of the disorder, and on the long-term effects of stimulant-drug treatment.

15-5 Do psychological disorders predict violent behavior?

Mental disorders seldom lead to violence, but when they do, they raise moral and ethical questions about whether society should hold people with disorders responsible for their violent actions. Most people with disorders are nonviolent and are more likely to be victims than attackers.

15-6 How many people have, or have had, a psychological disorder? Is poverty a risk factor?

Psychological disorder rates vary, depending on the time and place of the survey. In one multinational survey, the lowest rate of reported mental disorders was in Nigeria (6 percent), the highest rate in the United States (27 percent). Poverty is a risk factor. But some disorders, such as schizophrenia, can also drive people into poverty. Immigrants to the United States may average better mental health than their U.S. counterparts with the same ethnic heritage (a phenomenon known as the immigrant paradox).

Anxiety Disorders, OCD, and PTSD

15-7 How do generalized anxiety disorder, panic disorder, and phobias differ?

Anxiety disorders are psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. People with *generalized anxiety disorder* feel persistently and uncontrollably tense and apprehensive, for no apparent reason. In the more extreme *panic disorder*, anxiety escalates into periodic episodes of intense dread. Those with a *phobia* may be irrationally afraid of a specific object, activity, or situation.

15-8 What is OCD?

Persistent and repetitive thoughts (obsessions), actions (compulsions), or both characterize *obsessive-compulsive disorder (OCD)*.

15-9 What is PTSD?

Symptoms of *posttraumatic stress disorder (PTSD)* include four or more weeks of haunting memories, nightmares, hypervigilance, social withdrawal, jumpy anxiety, numbness of feeling, and/or sleep problems following some traumatic experience.

15-10 How do conditioning, cognition, and biology contribute to the feelings and thoughts that mark anxiety disorders, OCD, and PTSD?

The learning perspective views anxiety disorders, OCD, and PTSD as products of fear conditioning, stimulus generalization, fearful-behavior reinforcement, and observational

learning (usually with hypervigilance) of others' fears and cognitions. The biological perspective considers genetic predispositions for high levels of emotional reactivity and neurotransmitter production; abnormal responses in the brain's fear circuits; and the role that fears of life-threatening dangers played in natural selection and evolution.

Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury

15-11 How do major depressive disorder, persistent depressive disorder, and bipolar disorder differ?

A person with *major depressive disorder* experiences at least five symptoms of depression (including either depressed mood or loss of interest or pleasure) for two or more weeks. Persistent depressive disorder includes a long-lasting mildly depressed mood, along with at least two other symptoms. A person with the less common condition of *bipolar disorder* experiences not only depression but also *mania*—episodes of hyperactive and wildly optimistic, impulsive behavior.

15-12 How can the biological and social-cognitive perspectives help us understand depressive disorders and bipolar disorder?

The biological perspective on depressive disorders and bipolar disorder focuses on genetic predispositions, abnormalities in brain structures and function (including those found in neurotransmitter systems), and nutritional (and drug) effects. The social-cognitive perspective views depression as an ongoing cycle of stressful experiences (interpreted through negative beliefs, attributions, and memories, often with relentless *rumination*) leading to negative moods, thoughts, and actions, thereby fueling new stressful experiences.

15-13 What factors increase the risk of suicide, and what do we know about nonsuicidal self-injury?

Suicide rates differ by nation, race, gender, age group, income, religious involvement, marital status, and other factors. Those lacking social support, such as many gay, transgender, and gender nonconforming youth, are at increased risk, as are people who have been anxious or depressed. Forewarnings of suicide may include verbal hints, giving away possessions, withdrawal, and preoccupation with death. People who talk about suicide should be taken seriously: listen and empathize, connect them to help, and protect those who appear at immediate risk. Nonsuicidal self-injury (NSSI) does not usually lead to suicide but may escalate to suicidal thoughts and acts if untreated. People who engage in NSSI do not tolerate stress well and tend to be self-critical, with poor communication and problem-solving skills.

Schizophrenia

15-14 What patterns of perceiving, thinking, and feeling characterize schizophrenia?

Schizophrenia is a *psychotic disorder* characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression. Hallucinations are sensory experiences without sensory stimulation; *delusions* are false beliefs. Schizophrenia symptoms may be positive (the presence of inappropriate behaviors) or negative (the absence of appropriate behaviors).

15-15 How do chronic schizophrenia and acute schizophrenia differ?

Schizophrenia typically strikes during late adolescence, affects males slightly more often, and occurs in all cultures. In *chronic* (or process) *schizophrenia*, development is gradual and recovery is doubtful. In *acute* (or reactive) *schizophrenia*, onset is sudden—in reaction to stress—and prospects for recovery are brighter.

15-16 What brain abnormalities are associated with schizophrenia?

People with schizophrenia have an excess number of dopamine receptors, which may intensify brain signals, creating positive symptoms such as hallucinations and paranoia. Brain scans have revealed abnormal activity in the frontal lobes, thalamus, and amygdala, as well as a loss of neural connections across the brain network. Brain abnormalities associated with schizophrenia include enlarged, fluid-filled areas and corresponding shrinkage and thinning of cerebral tissue.

15-17 What prenatal events are associated with increased risk of developing schizophrenia?

Possible contributing factors include maternal diabetes, older paternal age, viral infections or famine conditions during the mother's pregnancy, and low weight or oxygen deprivation at birth.

15-18 How do genes influence schizophrenia? What factors may be early warning signs of schizophrenia in children?

Twin and adoption studies indicate that the predisposition to schizophrenia is inherited. Multiple genes interact to produce schizophrenia. No environmental causes invariably produce schizophrenia, but environmental events (such as prenatal viruses or maternal stress) may “turn on” genes in those who are predisposed to this disorder. Possible early warning signs include both biological factors (a mother with severe and long-lasting schizophrenia; birth complications; separation from parents; short attention span and poor muscle coordination) and psychological factors (disruptive or withdrawn behavior; emotional unpredictability; poor peer relations and solo play; separation from parents; childhood abuse).

Dissociative, Personality, and Eating Disorders

15-19 What are dissociative disorders, and why are they controversial?

Dissociative disorders are controversial, rare conditions in which conscious awareness seems to become separated from previous memories, thoughts, and feelings. Skeptics note that *dissociative identity disorder (DID)* increased dramatically in the late twentieth century; is rarely found outside North America; and may reflect role playing by people vulnerable to therapists' suggestions. Others view DID as a manifestation of feelings of anxiety, or as a response learned when behaviors are reinforced by anxiety-reduction.

15-20 What are the three clusters of personality disorders? What behaviors and brain activity characterize the antisocial personality?

Personality disorders are inflexible and enduring behavior patterns that impair social functioning. The ten DSM-5 disorders tend to form three clusters, characterized by (1) anxiety, (2) eccentric or odd behaviors, and (3) dramatic or impulsive behaviors. *Antisocial personality disorder* (one of those in the third cluster) is characterized by a lack of conscience and, sometimes, by aggressive and fearless behavior. The amygdala is smaller and the frontal lobes less active in people with this disorder, leading to impaired frontal lobe cognitive functions and decreased responsiveness to others' distress. Genetic predispositions may interact with the environment to produce these characteristics.

15-21 What are the three main eating disorders, and how do biological, psychological, and social-cultural influences make people more vulnerable to them?

In those with eating disorders (most often women or gay men), psychological factors overwhelm the body's tendency to maintain a normal weight. Despite being significantly underweight, people with *anorexia nervosa* (usually adolescent females) continue to diet and sometimes exercise excessively because they view themselves as fat. Those with *bulimia nervosa* (usually women in their late teens and early twenties) secretly binge and then compensate by purging, fasting, or excessively exercising. Those with *binge-eating disorder* binge but do not follow with purging, fasting, and exercising. Cultural pressures, low self-esteem, and negative emotions interact with stressful life experiences and genetics to produce eating disorders.

CHAPTER 16

THERAPY

Introduction to Therapy and the Psychological Therapies

16-1 How do *psychotherapy* and the *biomedical therapies* differ?

Psychotherapy is treatment involving psychological techniques that consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. The major psychotherapies derive from psychology's psychodynamic, humanistic, behavioral, and cognitive perspectives. *Biomedical therapy* treats psychological disorders with medications or procedures that act directly on a patient's physiology. An *eclectic approach* combines techniques from various forms of therapy.

16-2 What are the goals and techniques of psychoanalysis, and how have they been adapted in psychodynamic therapy?

Through *psychoanalysis*, Sigmund Freud tried to give people self-insight and relief from their disorders by bringing anxiety-laden feelings and thoughts into conscious awareness. Psychoanalytic techniques included using free association and *interpretation* of instances of *resistance* and *transference*. *Psychodynamic therapy* has been influenced by traditional psychoanalysis but differs from it in many ways, including the lack of belief in id, ego, and superego. This contemporary therapy is briefer, less expensive, and more focused on helping the client find relief from current symptoms. Psychodynamic therapists help clients understand how past relationships create themes that may be acted out in present relationships.

16-3 What are the basic themes of humanistic therapy? What are the specific goals and techniques of Rogers' client-centered approach?

Both psychodynamic and humanistic therapists are *insight therapies*—they attempt to improve functioning by increasing clients' awareness of motives and defenses. Humanistic therapy's goals include helping clients grow in self-awareness and self-acceptance; promoting personal growth rather than curing illness; helping clients take responsibility for their own growth; focusing on conscious thoughts rather than unconscious motivations; and seeing the present and future as more important than the past. Carl Rogers' *client-centered therapy* proposed that therapists' most important contributions are to function as a psychological mirror through *active listening* and to provide a growth-fostering environment of *unconditional positive regard*.

16-4 How does the basic assumption of behavior therapy differ from the assumptions of psychodynamic and humanistic therapies? What techniques are used in exposure therapies and aversive conditioning?

Behavior therapies are not insight therapies, and instead assume that problem behaviors *are* the problem. Their goal is to apply learning principles to modify these problem

behaviors. Classical conditioning techniques, including *exposure therapies* (such as *systematic desensitization* or *virtual reality exposure therapy*) and *aversive conditioning*, attempt to change behaviors through *counterconditioning*—evoking new responses to old stimuli that trigger unwanted behaviors.

16-5 What is the main premise of therapy based on operant conditioning principles, and what are the views of its proponents and critics?

Operant conditioning operates under the premise that voluntary behaviors are strongly influenced by their consequences. Therapy based on operant conditioning principles therefore uses behavior modification techniques to change unwanted behaviors by positively reinforcing desired behaviors and ignoring or punishing undesirable behaviors. Critics maintain that (1) techniques such as those used in *token economies* may produce behavior changes that disappear when rewards end, and (2) deciding which behaviors should change is authoritarian and unethical. Proponents argue that treatment with positive rewards is more humane than punishing people or institutionalizing them for undesired behaviors.

16-6 What are the goals and techniques of the cognitive therapies and of cognitive-behavioral therapy?

The *cognitive therapies*, such as Aaron Beck's cognitive therapy for depression, assume that our thinking influences our feelings, and that the therapist's role is to change clients' self-defeating thinking by training them to perceive and interpret events in more constructive ways. The widely researched and practiced *cognitive-behavioral therapy* (CBT) combines cognitive therapy and behavior therapy by helping clients regularly try out their new ways of thinking and behaving in their everyday life. A newer CBT variation, dialectical behavior therapy (DBT), teaches clients cognitive tactics for tolerating distress and regulating emotions, and trains them in social skills and mindfulness meditation.

16-7 What are the aims and benefits of group and family therapies?

Group therapy sessions can help more people with less cost than individual therapy. Clients may benefit from exploring feelings and developing social skills in a group situation, from learning that others have similar problems, and from getting feedback on new ways of behaving. *Family therapy* views a family as an interactive system. It attempts to help members discover the roles they play and learn to communicate more openly and directly.

Evaluating Psychotherapies

16-8 Does psychotherapy work? How can we know?

Clients' and therapists' positive testimonials cannot prove that psychotherapy is

effective, and the placebo effect makes it difficult to judge whether improvement occurred because of the treatment. Using *meta-analyses* to statistically combine the results of hundreds of randomized psychotherapy outcome studies, researchers have found that those not undergoing treatment often improve, but those undergoing psychotherapy are more likely to improve—and to improve more quickly and with less risk of relapse.

16-9 Are some psychotherapies more effective than others for specific disorders?

No one type of psychotherapy is generally superior to all others. Therapy is most effective for those with clear-cut, specific problems. Some therapies—such as behavior conditioning for treating phobias and compulsions—are more effective for specific disorders. Cognitive and cognitive-behavioral therapies have been effective in coping with anxiety, posttraumatic stress disorder, insomnia, and depression; behavioral conditioning therapies with specific behavior problems; psychodynamic therapy for depression and anxiety; and nondirective (client-centered) counseling for mild to moderate depression. *Evidence-based practice* integrates the best available research with clinicians' expertise and patients' characteristics and preferences.

16-10 How do alternative therapies fare under scientific scrutiny?

Abnormal states tend to return to normal on their own, and the placebo effect can create the impression that a treatment has been effective. These two tendencies complicate assessments of nontraditional therapies that claim to cure certain ailments. Eye movement desensitization and reprocessing (EMDR) has shown some effectiveness—but not from the eye movement (rather from the exposure therapy nature of the treatments). Light exposure therapy does seem to help those with a seasonal pattern in depression symptoms by activating a brain region that influences arousal and hormones.

16-11 What three elements are shared by all forms of psychotherapy?

All psychotherapies offer new hope for demoralized people; a fresh perspective; and (if the therapist is effective) an empathic, trusting, and caring relationship. The emotional bond of trust and understanding between therapist and client—the *therapeutic alliance*—is an important element in effective therapy.

16-12 How do culture and values influence the client-therapist relationship?

Therapists differ in the values that influence their goals in therapy and their views of progress. These differences may create problems if therapists and clients differ in their cultural or religious perspectives.

16-13 What should a person look for when selecting a psychotherapist?

Campus health centers are generally good starting points for counseling options, and they may offer some free services. A person seeking therapy may want to ask about the therapist's treatment approach, values, credentials, and fees. An important consideration

is whether the therapy seeker feels comfortable and able to establish a bond with the therapist. Recognizing the importance of a strong therapeutic alliance, the American Psychological Association accredits programs that provide training in cultural sensitivity and that recruit underrepresented cultural groups.

The Biomedical Therapies and Preventing Psychological Disorders

16-14 Why is therapeutic lifestyle change considered an effective biomedical therapy, and how does it work?

Therapeutic lifestyle change is considered a biomedical therapy because it influences the way the brain responds. Mind and body are a unit; affect one and you will affect the other. Our exercise, nutrition, relationships, recreation, relaxation, and religious or spiritual engagement affect our mental health. People who undergo a program of aerobic exercise, adequate sleep, light exposure, social engagement, rumination reduction, and better nutrition have gained relief from depressive symptoms.

16-15 What are the drug therapies? How do double-blind studies help researchers evaluate a drug's effectiveness?

Psychopharmacology has helped make drug therapy the most widely used biomedical therapy. *Antipsychotic drugs* are used in treating schizophrenia; some block dopamine activity. Side effects may include tardive dyskinesia (involuntary movements of facial muscles, tongue, and limbs) or increased risk of obesity and diabetes. *Antianxiety drugs*, which depress central nervous system activity, are used to treat anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder, and can be addictive. *Antidepressant drugs*, which often increase the availability of serotonin and norepinephrine, are used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder with modest effectiveness. Given their widening use (from depression to anxiety to strokes), some professionals prefer the term SSRIs (selective serotonin reuptake inhibitors) rather than antidepressants. Lithium and Depakote are mood stabilizers prescribed for those with bipolar disorder. Studies may use a double-blind procedure to avoid the placebo effect and researcher bias.

16-16 How are brain stimulation and psychosurgery used in treating specific disorders?

Electroconvulsive therapy (ECT), in which a brief electric current is sent through the brain of an anesthetized patient, is an effective, last-resort treatment for people with severe depression who have not responded to other therapy. Newer alternative treatments for depression include transcranial electrical stimulation (tDCS; also used for scientifically unproven cognitive benefits), *repetitive transcranial magnetic stimulation*

(*rTMS*), and deep-brain stimulation (DBS; said to work by calming an overactive brain region linked with negative emotions, and has shown benefit in some patients).

Psychosurgery removes or destroys brain tissue in hopes of modifying behavior. Radical psychosurgical procedures such as *lobotomy* are no longer performed. Today's microscale psychosurgery and MRI-guided precision brain surgery are rare, last-resort treatments because the effects are irreversible.

16-17 What is the rationale for preventive mental health programs, and why is it important to develop resilience?

Preventive mental health programs are based on the idea that many psychological disorders could be prevented by changing oppressive, esteem-destroying environments into more benevolent, nurturing environments that foster growth, self-confidence, and *resilience*. Struggling with challenges can lead to *posttraumatic growth*. Community psychologists work to prevent psychological disorders by turning destructive environments into more nurturing places that foster competence, health, and well-being.

APPENDIX A

PSYCHOLOGY AT WORK

A-1 What is *flow*?

Flow is a completely involved, focused state of consciousness with diminished awareness of self and time. It results from fully engaging one's skills. Interests predict both performance and persistence, so people should find vocations with a strong person-environment fit.

A-2 What are three key areas of study related to industrial-organizational psychology?

Three key areas of study related to *industrial-organizational (I/O) psychology* are *personnel*, *organizational*, and *human factors psychology*. Each uses psychological principles to study and benefit the wide range of today's workers, workplaces, and work activities.

A-3 How do personnel psychologists facilitate job seeking, employee selection, work placement, and performance appraisal?

Personnel psychologists work to provide training programs for job seekers; devise selection methods for new employees; recruit and evaluate applicants; design and evaluate training programs; identify people's interests and strengths; analyze job content; and appraise individual and organizational performance. Unstructured, subjective interviews foster the interviewer illusion; *structured interviews* pinpoint job-relevant strengths and are better predictors of performance. Checklists, graphic rating scales, and behavior rating scales are useful performance appraisal methods.

A-4 What is the role of organizational psychologists?

Organizational psychologists examine influences on worker satisfaction and productivity and facilitate organizational change. Employee satisfaction and engagement tend to correlate with organizational success; in fact, employee attitudes predict future business success.

A-5 How can leaders be most effective?

Effective leaders set specific challenging goals and choose an appropriate *leadership* style. Leadership style may be goal-oriented (*task leadership*), group-oriented (*social leadership*), or some combination of the two. Effective management often involves positive reinforcement, fulfilling the need to belong, and participative management.

A-6 What cultural influences need to be considered when choosing an effective leadership style?

Project GLOBE studies cultural variations in leadership expectation. Leaders who fulfill expectations (being directive in some cultures or participative in others) tend to be successful. But thriving companies worldwide tend to focus on identifying and enhancing employee strengths; strengths-based leadership pays dividends everywhere.

A-7 How do human factors psychologists work to create user-friendly machines and work settings?

Human factors psychologists contribute to human safety and improved design by encouraging developers and designers to consider human abilities and behaviors, to user-test their work before production and distribution, and to remain mindful of the curse of knowledge.

APPENDIX D Answers to *Master the Material* Questions

PROLOGUE

THE STORY OF PSYCHOLOGY

What Is Psychology?

1. Critical thinking is smart thinking. When evaluating media claims (even about topics you might not know much about), look for empirical evidence. Ask the following questions in your analysis: Are the claims based on scientific findings? Have several studies replicated the findings and confirmed them? Are any experts cited? If so, are they affiliated with a credible institution? Have they conducted or written about scientific research? What agenda might they have? What alternative explanations are possible?
2. Wilhelm Wundt
3. a
4. a
5. b
6. The environment (nurture) has an influence on us, but that influence is constrained by our biology (nature). Nature and nurture interact. People predisposed to be very tall (nature), for example, are unlikely to become Olympic gymnasts, no matter how hard they work (nurture).
7. b
8. positive psychology
9. d

- [3.](#) hypotheses
- [4.](#) c
- [5.](#) representative
- [6.](#) negative
- [7.](#) scatterplot
- [8.](#) a
- [9.](#) Regression toward the mean is a statistical phenomenon describing the tendency of extreme scores or outcomes to return to normal after an unusual event. Without knowing this, we may inaccurately decide the return to normal was a result of our own behavior.
- [10.](#) a
- [11.](#) (a) *Alcohol use is associated with violence. (One interpretation: Drinking triggers or unleashes aggressive behavior.)* Perhaps anger triggers drinking, or perhaps the same genes or child-raising practices are predisposing both drinking and aggression. (Here researchers have learned that drinking does indeed trigger aggressive behavior.)
(b) *Educated people live longer, on average, than less-educated people. (One interpretation: Education lengthens life and enhances health.)* Perhaps richer people can afford more education and better health care. (Research supports this conclusion.)
(c) *Teens engaged in team sports are less likely to use drugs, smoke, have sex, carry weapons, and eat junk food than are teens who do not engage in team sports. (One interpretation: Team sports encourage healthy living.)* Perhaps some third factor explains this correlation—teens who use drugs, smoke, have sex, carry weapons, and eat junk food may be “loners” who do not enjoy playing on any team.
(d) *Adolescents who frequently see smoking in movies are more likely to smoke. (One interpretation: Movie stars’ behavior influences impressionable teens.)* Perhaps

adolescents who smoke and attend movies frequently have less parental supervision and more access to spending money than other adolescents.

- [2.](#) a
- [3.](#) c
- [4.](#) c
- [5.](#) d
- [6.](#) Your brain constructs this perception of color in two stages. In the first stage, the lemon reflects light energy into your eyes, where it is transformed into neural messages. Three sets of cones, each sensitive to a different light frequency (red, blue, and green) process color. In this case, the light energy stimulates both red-sensitive and green-sensitive cones. In the second stage, opponent-process cells sensitive to paired opposites of color (red-green, yellow-blue, and black-white) evaluate the incoming neural messages as they pass through your optic nerve to the thalamus and visual cortex. When the yellow-sensitive opponent-process cells are stimulated, you identify the lemon as yellow.

The Nonvisual Senses

- [1.](#) cochlea
- [2.](#) The outer ear collects sound waves, which are translated into mechanical waves by the *middle ear* and turned into fluid waves in the *inner ear*. The auditory nerve then translates the energy into electrical waves and sends them to the brain, which perceives and interprets the sound.
- [3.](#) Place; frequency
- [4.](#) nociceptors
- [5.](#) c
- [6.](#) Our experience of pain is influenced by biological factors (such as genetic differences in endorphin production), psychological factors (such as our attention), and social-cultural factors (such as the presence of others).
- [7.](#) We have specialized receptors for detecting sweet, salty, sour, bitter, and umami tastes. Being able to detect pleasurable tastes enabled our ancestors to seek out energy- or protein-rich foods. Detecting aversive tastes deterred them from eating toxic substances, increasing their chances of survival.
- [8.](#) Kinesthesia; vestibular sense
- [9.](#) Your vestibular sense regulates balance and body positioning through kinesthetic receptors triggered by fluid in your inner ear. Wobbly legs and a spinning world are signs that these receptors are still responding to the ride's turbulence. As your vestibular sense adjusts to solid ground, your balance will be restored.
- [10.](#) d
- [11.](#) d

CHAPTER 7

LEARNING

Basic Learning Concepts and Classical Conditioning

- [1.](#) information; behaviors
- [2.](#) c
- [3.](#) conditioned
- [4.](#) discrimination
- [5.](#) b
- [6.](#) A sexual image is a US that triggers a UR of interest or arousal. Before the ad pairs a product with a sexual image, the product is an NS. Over time the product can become a CS that triggers the CR of interest or arousal.

Operant Conditioning

- [1.](#) Skinner
- [2.](#) shaping
- [3.](#) b
- [4.](#) Your instructor could reinforce your attentive behavior by taking away something you dislike. For example, your instructor could offer to shorten the length of an assigned paper or replace standard lecture time with an interesting in-class activity. In both cases, the instructor would remove something aversive to negatively reinforce your focused attention.
- [5.](#) partial (intermittent)
- [6.](#) a
- [7.](#) variable-interval
- [8.](#) c

Biology, Cognition, and Learning

- [1.](#) taste-aversion
- [2.](#) This finding supports Darwin's principle that natural selection favors traits that aid survival.
- [3.](#) cognitive map
- [4.](#) latent learning
- [5.](#) observational learning
- [6.](#) vicarious; vicarious
- [7.](#) a
- [8.](#) mirror
- [9.](#) c

CHAPTER 8

MEMORY

Studying and Encoding Memories

- [1.](#) recall
- [2.](#) encoding; storage; retrieval
- [3.](#) a
- [4.](#) iconic; echoic
- [5.](#) seven
- [6.](#) mnemonics

Storing and Retrieving Memories

- [1.](#) a
- [2.](#) implicit
- [3.](#) c
- [4.](#) retrieval cues
- [5.](#) Memories are stored within a web of many associations, one of which is mood. When you recall happy moments from your past, you activate these positive links. You may then experience mood-congruent memory and recall other happy moments, which could improve your mood and brighten your interpretation of current events.
- [6.](#) a

Forgetting, Memory Construction, and Improving Memory

- [1.](#) d
- [2.](#) d
- [3.](#) retroactive
- [4.](#) repression
- [5.](#) b

6. Eliza's immature hippocampus and minimal verbal skills would have prevented her from encoding an explicit memory of the wedding reception at the age of two. It's more likely that Eliza learned information (from hearing the story repeatedly) that she eventually constructed into a memory that feels very real.

7. source amnesia

8. déjà vu

9. b

10. b

CHAPTER 9

THINKING AND LANGUAGE

Thinking

1. concept
2. algorithm
3. Oscar will need to guard against *confirmation bias* (searching for support for his own views and ignoring contradictory evidence) as he seeks out opposing viewpoints. Even if Oscar encounters new information that disproves his beliefs, *belief perseverance* may lead him to cling to these views anyway. It will take more compelling evidence to change his political beliefs than it took to create them.
4. c
5. availability
6. framing
7. b

Language and Thought

1. c
2. phonemes; morphemes; grammar
3. telegraphic speech
4. universal grammar
5. a

CHAPTER 10

INTELLIGENCE

What Is Intelligence?

1. general intelligence (*g*)
2. c
3. academic; practical; creative
4. d

Assessing Intelligence

1. d
2. c
3. reliability

The Dynamics of Intelligence

1. Writers' work relies more on crystallized intelligence, or accumulated knowledge, which increases with age. For top performance, scientists doing research may need more fluid intelligence (speedy and abstract reasoning), which tends to decrease with age.
2. c

Genetic and Environmental Influences on Intelligence

1. a
2. c
3. c
4. Stereotype threat

CHAPTER 11

WHAT DRIVES US: HUNGER, SEX, BELONGING, and ACHIEVEMENT

Basic Motivational Concepts

1. b
2. a
3. incentive
4. Arousal
5. b
6. a

Hunger

1. Maslow's hierarchy of needs supports this statement because it addresses the primacy of some motives over others. Once our basic physiological needs are met, safety concerns are addressed next, followed by belongingness and love needs (such as the desire to kiss).
2. set point
3. c
4. low
5. basal metabolic
6. d
7. Sanjay's plan is problematic. After he gains weight, the extra fat will require less energy to maintain than it did to gain in the first place. Sanjay may have a hard time getting rid of it later, when his metabolism slows down in an effort to retain his body weight.

Sexual Motivation

1. b

- [2.](#) b
- [3.](#) Sexual dysfunctions are problems that consistently impair sexual arousal or sexual function. Paraphilias are conditions, which may be classified as psychological disorders, in which sexual arousal is associated with nonhuman objects, the suffering of self or others, and/or nonconsenting persons.
- [4.](#) does; doesn't
- [5.](#) c

Affiliation and Achievement

- [1.](#) c
- [2.](#) Monitor our time spent online, as well as our feelings about that time. Hide distracting online friends when necessary. Turn off or put away distracting devices. Get outside and away from technology regularly.

CHAPTER 12

EMOTIONS, STRESS, AND HEALTH

Introduction to Emotion

1. James-Lange
2. b
3. c
4. A polygraph measures emotion-linked physiological changes, such as breathing, heart rate, and perspiration. But the measure cannot distinguish between emotions with similar physiology (such as anxiety and guilt).

Expressing Emotion

1. facial feedback
2. Aiden's droopy posture could negatively affect his mood thanks to the behavior feedback effect, which tends to make us feel the way we act.

Experiencing Emotion

1. d
2. Positive
3. b
4. relative deprivation

Stress and Illness

1. resistance; exhaustion
2. tend; befriend
3. b
4. d

[5.](#) lymphocytes

[6.](#) c

[7.](#) Type A individuals frequently experience negative emotions (anger, impatience), during which the sympathetic nervous system diverts blood away from the liver. This leaves fat and cholesterol circulating in the bloodstream for deposit near the heart and other organs, increasing the risk of heart disease and other health problems. Thus, Type A individuals actually harm themselves by directing anger at others.

Health and Coping

[1.](#) emotion

[2.](#) b

[3.](#) internal

[4.](#) d

[5.](#) aerobic

[6.](#) c

CHAPTER 13

SOCIAL PSYCHOLOGY

Social Thinking

- [1.](#) a
- [2.](#) peripheral
- [3.](#) foot-in-the-door
- [4.](#) Cognitive dissonance theory best supports this suggestion. If Jamal acts confident, his behavior will contradict his negative self-thoughts, creating cognitive dissonance. To relieve the tension, Jamal may realign his attitudes with his actions by viewing himself as more outgoing and confident.

Social Influence

- [1.](#) c
- [2.](#) a
- [3.](#) The presence of a large audience generates arousal and strengthens Dr. Huang's most likely response: enhanced performance on a task he has mastered (teaching music history) and impaired performance on a task he finds difficult (statistics).
- [4.](#) deindividuation
- [5.](#) group polarization

Antisocial Relations

- [1.](#) stereotypes
- [2.](#) This reaction could occur because we tend to overgeneralize from vivid, memorable cases.
- [3.](#) more
- [4.](#) d
- [5.](#) c
- [6.](#) c

7. c

Prosocial Relations

1. mere exposure
2. companionate; passionate
3. d
4. c
5. mirror-image
6. superordinate

CHAPTER 14

PERSONALITY

Introduction to Personality and Psychodynamic Theories

- [1.](#) repression
- [2.](#) c
- [3.](#) superego
- [4.](#) b
- [5.](#) anxiety
- [6.](#) Projective
- [7.](#) d
- [8.](#) a
- [9.](#) a

Humanistic Theories and Trait Theories

- [1.](#) d
- [2.](#) Rogers might assert that the criminal was raised in an environment lacking genuineness, acceptance (unconditional positive regard), and empathy, which inhibited psychological growth and led to a negative self-concept.
- [3.](#) unconditional positive regard
- [4.](#) Trait
- [5.](#) c
- [6.](#) b
- [7.](#) b

Social-Cognitive Theories and the Self

- [1.](#) a
- [2.](#) social-cognitive

3. b

4. Yes, if that self-love is of the *secure* type. Secure self-esteem promotes a focus beyond the self and a higher quality of life. Excessive self-love may promote artificially high or defensive self-esteem, which is fragile; perceived threats may be met with anger or aggression.

5. spotlight effect

CHAPTER 15

PSYCHOLOGICAL DISORDERS

Introduction to Psychological Disorders

1. depression
2. No. Anna's behavior is unusual, causes her distress, and may make her a few minutes late on occasion, but it does not appear to significantly disrupt her ability to function. Like most of us, Anna demonstrates some unusual behaviors. Since they are not disabling or dysfunctional, they do not suggest a psychological disorder.
3. *Susto* is a condition marked by severe anxiety, restlessness, and fear of black magic. It is culture-specific to Latin America.
4. medical
5. c
6. Critics have expressed concerns about the negative effects of the DSM's labeling. Critics suggest the DSM-5 casts too wide a net on disorders, pathologizing normal behavior.
7. poverty
8. d

Anxiety Disorders, OCD, and PTSD

1. phobia
2. c
3. obsessive-compulsive
4. b
5. c

Depressive Disorders, Bipolar Disorder, Suicide, and Self-Injury

1. women's; men's

- [2.](#) d
- [3.](#) norepinephrine; serotonin
- [4.](#) social-cognitive

Schizophrenia

- [1.](#) No. Schizophrenia involves the altered perceptions, emotions, and behaviors of a mind split from reality. It does not involve the rapid changes in mood or identity suggested by this comparison.
- [2.](#) b
- [3.](#) hallucination
- [4.](#) a

Dissociative, Personality, and Eating Disorders

- [1.](#) c
- [2.](#) c
- [3.](#) b
- [4.](#) b

CHAPTER 16

THERAPY

Introduction to Therapy and the Psychological Therapies

- [1.](#) a
- [2.](#) Insight
- [3.](#) d
- [4.](#) active listening
- [5.](#) c
- [6.](#) counterconditioning
- [7.](#) systematic desensitization
- [8.](#) Behavior therapies are often the best choice for treating phobias. Viewing Rico's fear of the freeway as a learned response, a behavior therapist might help Rico learn to replace his anxious response to freeway driving with a relaxation response.
- [9.](#) token economy
- [10.](#) d
- [11.](#) Cognitive-behavioral
- [12.](#) b

Evaluating Psychotherapies

- [1.](#) c
- [2.](#) d
- [3.](#) research evidence, clinical expertise, and knowledge of the patient
- [4.](#) The placebo effect is the healing power of belief in a treatment. When patients expect a treatment to be effective, they may believe it was.

The Biomedical Therapies and Preventing Psychological Disorders

- [1.](#) c
- [2.](#) antianxiety
- [3.](#) lithium
- [4.](#) b
- [5.](#) d

APPENDIX A

PSYCHOLOGY AT WORK

- [1.](#) flow
- [2.](#) Personnel; human factors
- [3.](#) a
- [4.](#) d
- [5.](#) Focusing on specific, short-term goals, such as maintaining a regular study schedule, will be more helpful than focusing on more distant general goals, such as earning a good grade in this class.
- [6.](#) transformational
- [7.](#) c
- [8.](#) d

Glossary

absolute threshold

the minimum stimulus energy needed to detect a particular stimulus 50 percent of the time. ([p. 214](#))

accommodation

(1) in developmental psychology, adapting our current understandings (schemas) to incorporate new information. (2) in sensation and perception, the process by which the eye's lens changes shape to focus near or far objects on the retina. (pp. 175, 224)

achievement motivation

a desire for significant accomplishment; for mastery of skills or ideas; for control; and for attaining a high standard. ([p. 422](#))

achievement test

a test designed to assess what a person has learned. ([p. 365](#))

acquisition

in classical conditioning, the initial stage, when one links a neutral stimulus and an unconditioned stimulus so that the neutral stimulus begins triggering the conditioned response. In operant conditioning, the strengthening of a reinforced response. ([p. 267](#))

action potential

a neural impulse; a brief electrical charge that travels down an axon. ([p. 53](#))

active listening

empathic listening in which the listener echoes, restates, and clarifies. A feature of Rogers' client-centered therapy. ([p. 613](#))

acute schizophrenia

(also called *reactive schizophrenia*) a form of schizophrenia that can begin at any age, frequently occurs in response to an emotionally traumatic event, and has extended recovery periods. ([p. 594](#))

adaptation-level phenomenon

our tendency to form judgments (of sounds, of lights, of income) relative to a neutral level defined by our prior experience. ([p. 447](#))

adolescence

the transition period from childhood to adulthood, extending from puberty to independence. ([p. 192](#))

adrenal [ah-DREEN-el] glands

a pair of endocrine glands that sit just above the kidneys and secrete hormones (epinephrine and norepinephrine) that help arouse the body in times of stress. ([p. 62](#))

aerobic exercise

sustained exercise that increases heart and lung fitness; also helps alleviate depression and anxiety. ([p. 469](#))

affiliation need

the need to build relationships and to feel part of a group. ([p. 417](#))

aggression

any physical or verbal behavior intended to harm someone physically or emotionally. (pp. 152, 504)

agonist

a molecule that increases a neurotransmitter's action. ([p. 57](#))

AIDS (acquired immune deficiency syndrome)

a life-threatening, sexually transmitted infection caused by the *human immunodeficiency virus* (HIV). AIDS depletes the immune system, leaving the person vulnerable to infections. ([p. 406](#))

alcohol use disorder

(popularly known as *alcoholism*) alcohol use marked by tolerance, withdrawal, and a drive to continue problematic use. ([p. 115](#))

algorithm

a methodical, logical rule or procedure that guarantees solving a particular problem. Contrasts with the usually speedier—but also more error-prone—use of *heuristics*. ([p. 331](#))

all-or-none response

a neuron's reaction of either firing (with a full-strength response) or not firing. ([p. 55](#))

alpha waves

the relatively slow brain waves of a relaxed, awake state. ([p. 96](#))

altruism

unselfish regard for the welfare of others. ([p. 516](#))

Alzheimer's disease

a neurocognitive disorder marked by neural plaques, often with onset after age 80, and entailing a progressive decline in memory and other cognitive abilities. ([p. 207](#))

amphetamines

drugs that stimulate neural activity, causing accelerated body functions and associated energy and mood changes. ([p. 118](#))

amygdala

[uh-MIG-duh-la] two lima-bean-sized neural clusters in the limbic system; linked to emotion. ([p. 70](#))

androgyny

displaying both traditional masculine and feminine psychological characteristics. ([p. 161](#))

anorexia nervosa

an eating disorder in which a person (usually an adolescent female) maintains a starvation diet despite being significantly underweight; sometimes accompanied by excessive exercise. ([p. 605](#))

antagonist

a molecule that inhibits or blocks a neurotransmitter's action. ([p. 59](#))

anterograde amnesia

an inability to form new memories. ([p. 317](#))

antianxiety drugs

drugs used to control anxiety and agitation. ([p. 637](#))

antidepressant drugs

drugs used to treat depression, anxiety disorders, obsessive-compulsive disorder, and posttraumatic stress disorder. (Several widely used antidepressant drugs are *selective serotonin reuptake inhibitors*—SSRIs.) ([p. 637](#))

antipsychotic drugs

drugs used to treat schizophrenia and other forms of severe thought disorder. ([p. 637](#))

antisocial personality disorder

a personality disorder in which a person (usually a man) exhibits a lack of conscience for wrongdoing, even toward friends and family members; may be aggressive and ruthless or a clever con artist. ([p. 602](#))

anxiety disorders

psychological disorders characterized by distressing, persistent anxiety or maladaptive behaviors that reduce anxiety. ([p. 573](#))

aphasia

impairment of language, usually caused by left hemisphere damage either to Broca's area (impairing speaking) or to Wernicke's area (impairing understanding). ([p. 351](#))

applied research

scientific study that aims to solve practical problems. ([p. 15](#))

aptitude test

a test designed to predict a person's future performance; *aptitude* is the capacity to learn. ([p. 365](#))

asexual

having no sexual attraction to others. ([p. 403](#))

assimilation

interpreting our new experiences in terms of our existing schemas. ([p. 175](#))

association areas

areas of the cerebral cortex that are not involved in primary motor or sensory functions; rather, they are involved in higher mental functions such as learning, remembering, thinking, and speaking. ([p. 79](#))

associative learning

learning that certain events occur together. The events may be two stimuli (as in classical conditioning) or a response and its consequence (as in operant conditioning). ([p. 262](#))

attachment

an emotional tie with another person; shown in young children by their seeking closeness to their caregiver and showing distress on separation. ([p. 183](#))

attention-deficit/hyperactivity disorder (ADHD)

a psychological disorder marked by extreme inattention and/or hyperactivity and impulsivity. ([p. 566](#))

attitude

feelings, often influenced by our beliefs, that predispose us to respond in a particular way to objects, people, and events. ([p. 480](#))

attribution theory

the theory that we explain someone's behavior by crediting either the situation or the person's disposition. ([p. 478](#))

audition

the sense or act of hearing. ([p. 242](#))

autism spectrum disorder (ASD)

a disorder that appears in childhood and is marked by significant deficiencies in communication and social interaction, and by rigidly fixated interests and repetitive behaviors. ([p. 180](#))

automatic processing

unconscious encoding of incidental information, such as space, time, and frequency, and of well-learned information, such as word meanings. ([p. 300](#))

autonomic [aw-tuh-NAHM-ik] nervous system (ANS)

the part of the peripheral nervous system that controls the glands and the muscles of the internal organs (such as the heart). Its sympathetic division arouses; its parasympathetic division calms. ([p. 59](#))

availability heuristic

estimating the likelihood of events based on their availability in memory; if instances come readily to mind (perhaps because of their vividness), we presume such events are common. ([p. 333](#))

aversive conditioning

associates an unpleasant state (such as nausea) with an unwanted behavior (such as drinking alcohol). ([p. 617](#))

axon

the neuron extension that passes messages through its branches to other neurons or to muscles or glands. ([p. 53](#))

babbling stage

beginning around 4 months, the stage of speech development in which an infant spontaneously utters various sounds at first unrelated to the household language. ([p. 347](#))

barbiturates

drugs that depress central nervous system activity, reducing anxiety but impairing memory and judgment. ([p. 115](#))

basal metabolic rate

the body's resting rate of energy output. ([p. 398](#))

basic research

pure science that aims to increase the scientific knowledge base. ([p. 15](#))

basic trust

according to Erik Erikson, a sense that the world is predictable and trustworthy; said to be formed during infancy by appropriate experiences with responsive caregivers. ([p. 186](#))

behavior feedback effect

the tendency of behavior to influence our own and others' thoughts, feelings, and actions. ([p. 440](#))

behavior genetics

the study of the relative power and limits of genetic and environmental influences on behavior. (pp. 10, 129)

behavior therapy

therapy that applies learning principles to the elimination of unwanted behaviors. ([p. 615](#))

behaviorism

the view that psychology (1) should be an objective science that (2) studies behavior without reference to mental processes. Most psychologists today agree with (1) but not with (2). (pp. 9, 265)

belief perseverance

clinging to one's initial conceptions after the basis on which they were formed has been discredited. ([p. 337](#))

binge-eating disorder

significant binge-eating episodes, followed by distress, disgust, or guilt, but without the compensatory behavior that marks bulimia nervosa. ([p. 605](#))

binocular cue

a depth cue, such as retinal disparity, that depends on the use of two eyes. ([p. 234](#))

biological psychology

the scientific study of the links between biological (genetic, neural, hormonal) and psychological processes. Some biological psychologists call themselves *behavioral neuroscientists*, *neuropsychologists*, *behavior geneticists*, *physiological psychologists*, or *biopsychologists*. ([p. 51](#))

biomedical therapy

prescribed medications or procedures that act directly on the person's physiology. ([p. 611](#))

biopsychosocial approach

an integrated approach that incorporates biological, psychological, and social-cultural levels of analysis. ([p. 12](#))

bipolar disorder

a disorder in which a person alternates between the hopelessness and lethargy of depression and the overexcited state of mania. (Formerly called *manic-depressive disorder*.) ([p. 582](#))

blind spot

the point at which the optic nerve leaves the eye, creating a “blind” spot because no receptor cells are located there. ([p. 227](#))

blindsight

a condition in which a person can respond to a visual stimulus without consciously experiencing it. ([p. 93](#))

bottom-up processing

analysis that begins with the sensory receptors and works up to the brain's integration of sensory information. ([p. 214](#))

brainstem

the oldest part and central core of the brain, beginning where the spinal cord swells as it enters the skull; the brainstem is responsible for automatic survival functions. ([p. 68](#))

Broca's area

helps control language expression—an area of the frontal lobe, usually in the left hemisphere, that directs the muscle movements involved in speech. ([p. 351](#))

bulimia nervosa

an eating disorder in which a person's binge eating (usually of high-calorie foods) is followed by inappropriate weight-loss promoting behavior, such as vomiting, laxative use, fasting, or excessive exercise. ([p. 605](#))

bystander effect

the tendency for any given bystander to be less likely to give aid if other bystanders are present. ([p. 518](#))

Cannon-Bard theory

the theory that an emotion-arousing stimulus simultaneously triggers (1) physiological responses and (2) the subjective experience of emotion. ([p. 427](#))

case study

a descriptive technique in which one individual or group is studied in depth in the hope of revealing universal principles. ([p. 26](#))

catharsis

in psychology, the idea that “releasing” aggressive energy (through action or fantasy) relieves aggressive urges. ([p. 443](#))

cell body

the part of a neuron that contains the nucleus; the cell’s life-support center. ([p. 52](#))

central nervous system (CNS)

the brain and spinal cord. ([p. 59](#))

central route persuasion

occurs when interested people focus on the arguments and respond with favorable thoughts. ([p. 480](#))

cerebellum [sehr-uh-BELL-um]

the “little brain” at the rear of the brainstem; functions include processing sensory input, coordinating movement output and balance, and enabling nonverbal learning and memory. ([p. 69](#))

cerebral [seh-REE-bruhl] cortex

the intricate fabric of interconnected neural cells covering the cerebral hemispheres; the body’s ultimate control and information-processing center. ([p. 75](#))

change blindness

failing to notice changes in the environment; a form of *inattentional blindness*. ([p. 91](#))

chromosomes

threadlike structures made of DNA molecules that contain the genes. ([p. 129](#))

chronic schizophrenia

(also called *process schizophrenia*) a form of schizophrenia in which symptoms usually appear by late adolescence or early adulthood. As

people age, psychotic episodes last longer and recovery periods shorten. ([p. 594](#))

chunking

organizing items into familiar, manageable units; often occurs automatically. ([p. 302](#))

circadian [ser-KAY-dee-an] rhythm

our biological clock; regular bodily rhythms (for example, of temperature and wakefulness) that occur on a 24-hour cycle. ([p. 96](#))

classical conditioning

a type of learning in which we link two or more stimuli; as a result, to illustrate with Pavlov's classic experiment, the first stimulus (a tone) comes to elicit behavior (drooling) in anticipation of the second stimulus (food). ([p. 265](#))

client-centered therapy

a humanistic therapy, developed by Carl Rogers, in which the therapist uses techniques such as *active listening* within an accepting, genuine, empathic environment to facilitate clients' growth. (Also called *person-centered therapy*.) ([p. 613](#))

clinical psychology

a branch of psychology that studies, assesses, and treats people with psychological disorders. ([p. 15](#))

cocaine

a powerful and addictive stimulant derived from the coca plant; produces temporarily increased alertness and euphoria. ([p. 118](#))

cochlea

[KOHK-lee-uh] a coiled, bony, fluid-filled tube in the inner ear; sound waves traveling through the cochlear fluid trigger nerve impulses. ([p. 243](#))

cochlear implant

a device for converting sounds into electrical signals and stimulating the auditory nerve through electrodes threaded into the cochlea. ([p. 244](#))

cognition

all the mental activities associated with thinking, knowing, remembering, and communicating. (pp. 175, 331)

cognitive dissonance theory

the theory that we act to reduce the discomfort (dissonance) we feel when two of our thoughts (cognitions) are inconsistent. For example, when we become aware that our attitudes and our actions clash, we can reduce the resulting dissonance by changing our attitudes. ([p. 482](#))

cognitive learning

the acquisition of mental information, whether by observing events, by watching others, or through language. ([p. 265](#))

cognitive map

a mental representation of the layout of one's environment. For example, after exploring a maze, rats act as if they have learned a cognitive map of it. ([p. 286](#))

cognitive neuroscience

the interdisciplinary study of the brain activity linked with cognition (including perception, thinking, memory, and language). (pp. 9, 88)

cognitive psychology

the study of mental processes, such as occur when we perceive, learn, remember, think, communicate, and solve problems. ([p. 9](#))

cognitive therapy

therapy that teaches people new, more adaptive ways of thinking; based on the assumption that thoughts intervene between events and our emotional reactions. ([p. 619](#))

cognitive-behavioral therapy (CBT)

a popular integrative therapy that combines cognitive therapy (changing self-defeating thinking) with behavior therapy (changing behavior). ([p. 621](#))

cohort

a group of people sharing a common characteristic, such as from a given time period. ([p. 372](#))

collective unconscious

Carl Jung's concept of a shared, inherited reservoir of memory traces from our species' history. ([p. 533](#))

collectivism

giving priority to the goals of one's group (often one's extended family or work group) and defining one's identity accordingly. ([p. 148](#))

community psychology

a branch of psychology that studies how people interact with their social environments and how social institutions affect individuals and groups. ([p. 15](#))

companionate love

the deep affectionate attachment we feel for those with whom our lives are intertwined. ([p. 516](#))

concept

a mental grouping of similar objects, events, ideas, or people. ([p. 331](#))

concrete operational stage

in Piaget's theory, the stage of cognitive development (from about 7 to 11 years of age) during which children gain the mental operations that enable them to think logically about concrete events. ([p. 179](#))

conditioned reinforcer

a stimulus that gains its reinforcing power through its association with a primary reinforcer; also known as a *secondary reinforcer*. ([p. 275](#))

conditioned response (CR)

in classical conditioning, a learned response to a previously neutral (but now conditioned) stimulus (CS). ([p. 267](#))

conditioned stimulus (CS)

in classical conditioning, an originally neutral stimulus that, after association with an unconditioned stimulus (US), comes to trigger a conditioned response (CR). ([p. 267](#))

conduction hearing loss

a less common form of hearing loss, caused by damage to the mechanical system that conducts sound waves to the cochlea. ([p. 244](#))

cones

retinal receptors that are concentrated near the center of the retina and that function in daylight or in well-lit conditions. Cones detect fine detail and give rise to color sensations. ([p. 227](#))

confirmation bias

a tendency to search for information that supports our preconceptions and to ignore or distort contradictory evidence. ([p. 331](#))

conflict

a perceived incompatibility of actions, goals, or ideas. ([p. 521](#))

conformity

adjusting our behavior or thinking to coincide with a group standard. ([p. 485](#))

confounding variable

a factor other than the factor being studied that might influence a study's results. ([p. 35](#))

consciousness

our subjective awareness of ourselves and our environment. ([p. 88](#))

conservation

the principle (which Piaget believed to be a part of concrete operational reasoning) that properties such as mass, volume, and number remain the same despite changes in the forms of objects. ([p. 177](#))

content validity

the extent to which a test samples the behavior that is of interest. ([p. 370](#))

continuous reinforcement schedule

reinforcing the desired response every time it occurs. ([p. 276](#))

control group

in an experiment, the group *not* exposed to the treatment; contrasts with the experimental group and serves as a comparison for evaluating the effect of the treatment. ([p. 34](#))

convergent thinking

narrowing the available problem solutions to determine the single best solution. ([p. 339](#))

coping

alleviating stress using emotional, cognitive, or behavioral methods. ([p. 463](#))

coronary heart disease

the clogging of the vessels that nourish the heart muscle; the leading cause of death in many developed countries. ([p. 458](#))

corpus callosum [KOR-pus kah-LOW-sum]

the large band of neural fibers connecting the two brain hemispheres and carrying messages between them. ([p. 82](#))

correlation

a measure of the extent to which two factors vary together, and thus of how well either factor predicts the other. ([p. 29](#))

correlation coefficient

a statistical index of the relationship between two things (from -1.00 to $+1.00$). ([p. 29](#))

counseling psychology

a branch of psychology that assists people with problems in living (often related to school, work, or marriage) and in achieving greater well-being. ([p. 15](#))

counterconditioning

behavior therapy procedures that use classical conditioning to evoke new responses to stimuli that are triggering unwanted behaviors; include *exposure therapies* and *aversive conditioning*. ([p. 615](#))

creativity

the ability to produce new and valuable ideas. ([p. 339](#))

critical period

an optimal period early in the life of an organism when exposure to certain stimuli or experiences produces normal development. ([p. 185](#))

critical thinking

thinking that does not blindly accept arguments and conclusions. Rather, it examines assumptions, appraises the source, discerns hidden biases, evaluates evidence, and assesses conclusions. ([p. 3](#))

cross-sectional study

research that compares people of different ages at the same point in time. (pp. 207, 372)

crystallized intelligence

our accumulated knowledge and verbal skills; tends to increase with age. ([p. 372](#))

culture

the enduring behaviors, ideas, attitudes, values, and traditions shared by a group of people and transmitted from one generation to the next. (pp. 11, 147)

debriefing

the postexperimental explanation of a study, including its purpose and any deceptions, to its participants. ([p. 38](#))

deep processing

encoding semantically, based on the meaning of the words; tends to

yield the best retention. ([p. 305](#))

defense mechanisms

in psychoanalytic theory, the ego's protective methods of reducing anxiety by unconsciously distorting reality. ([p. 531](#))

deindividuation

the loss of self-awareness and self-restraint occurring in group situations that foster arousal and anonymity. ([p. 493](#))

déjà vu

that eerie sense that "I've experienced this before." Cues from the current situation may unconsciously trigger retrieval of an earlier experience. ([p. 322](#))

delta waves

the large, slow brain waves associated with deep sleep. ([p. 98](#))

delusion

a false belief, often of persecution or grandeur, that may accompany psychotic disorders. ([p. 593](#))

dendrites

a neuron's often bushy, branching extensions that receive and integrate messages, conducting impulses toward the cell body. ([p. 52](#))

dependent variable

in an experiment, the outcome that is measured; the variable that may change when the independent variable is manipulated. ([p. 35](#))

depressants

drugs (such as alcohol, barbiturates, and opiates) that reduce neural activity and slow body functions. ([p. 115](#))

depth perception

the ability to see objects in three dimensions although the images that strike the retina are two-dimensional; allows us to judge distance. ([p. 234](#))

developmental psychology

a branch of psychology that studies physical, cognitive, and social change throughout the life span. ([p. 166](#))

difference threshold

the minimum difference between two stimuli required for detection 50 percent of the time. We experience the difference threshold as a *just*

noticeable difference (or *jnd*). ([p. 216](#))

discrimination

(1) in classical conditioning, the learned ability to distinguish between a conditioned stimulus and similar stimuli that do not signal an unconditioned stimulus. (In operant conditioning, the ability to distinguish responses that are reinforced from similar responses that are not reinforced.) (2) in social psychology, unjustifiable negative behavior toward a group and its members. (pp. 269, 497)

dissociation

a split in consciousness, which allows some thoughts and behaviors to occur simultaneously with others. ([p. 250](#))

dissociative disorders

controversial, rare disorders in which conscious awareness becomes separated (dissociated) from previous memories, thoughts, and feelings. ([p. 599](#))

dissociative identity disorder (DID)

a rare dissociative disorder in which a person exhibits two or more distinct and alternating personalities. (Formerly called *multiple personality disorder*.) ([p. 600](#))

divergent thinking

expanding the number of possible problem solutions; creative thinking that diverges in different directions. ([p. 339](#))

DNA (deoxyribonucleic acid)

a complex molecule containing the genetic information that makes up the chromosomes. ([p. 129](#))

double-blind procedure

an experimental procedure in which both the research participants and the research staff are ignorant (blind) about whether the research participants have received the treatment or a placebo. Commonly used in drug-evaluation studies. ([p. 34](#))

dream

a sequence of images, emotions, and thoughts passing through a sleeping person's mind. ([p. 107](#))

drive-reduction theory

the idea that a physiological need creates an aroused state (a drive) that motivates an organism to satisfy the need. ([p. 391](#))

DSM-5

the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition; a widely used system for classifying psychological disorders. ([p. 564](#))

dual processing

the principle that information is often simultaneously processed on separate conscious and unconscious tracks. ([p. 93](#))

echoic memory

a momentary sensory memory of auditory stimuli; if attention is elsewhere, sounds and words can still be recalled within 3 or 4 seconds. ([p. 300](#))

eclectic approach

an approach to psychotherapy that uses techniques from various forms of therapy. ([p. 611](#))

Ecstasy (MDMA)

a synthetic stimulant and mild hallucinogen. Produces euphoria and social intimacy, but with short-term health risks and longer-term harm to serotonin-producing neurons and to mood and cognition. ([p. 118](#))

effortful processing

encoding that requires attention and conscious effort. ([p. 300](#))

ego

the largely conscious, “executive” part of personality that, according to Freud, mediates among the demands of the id, superego, and reality. The ego operates on the *reality principle*, satisfying the id's desires in ways that will realistically bring pleasure rather than pain. ([p. 530](#))

egocentrism

in Piaget's theory, the preoperational child's difficulty taking another's point of view. ([p. 177](#))

electroconvulsive therapy (ECT)

a biomedical therapy for severely depressed patients in which a brief electric current is sent through the brain of an anesthetized patient. ([p. 639](#))

electroencephalogram (EEG)

an amplified recording of the waves of electrical activity sweeping across the brain's surface. These waves are measured by electrodes

placed on the scalp. ([p. 65](#))

embodied cognition

the influence of bodily sensations, gestures, and other states on cognitive preferences and judgments. ([p. 255](#))

embryo

the developing human organism from about 2 weeks after fertilization through the second month. ([p. 168](#))

emerging adulthood

a period from about age 18 to the mid-twenties, when many in Western cultures are no longer adolescents but have not yet achieved full independence as adults. ([p. 200](#))

emotion

a response of the whole organism, involving (1) physiological arousal, (2) expressive behaviors, and (3) conscious experience. ([p. 427](#))

emotional intelligence

the ability to perceive, understand, manage, and use emotions. ([p. 363](#))

emotion-focused coping

attempting to alleviate stress by avoiding or ignoring a stressor and attending to emotional needs related to our stress reaction. ([p. 463](#))

empirical approach

an evidence-based method that draws on observation and experimentation. ([p. 3](#))

empirically derived test

a test (such as the MMPI) created by selecting from a pool of items those that discriminate between groups. ([p. 545](#))

encoding

the process of getting information into the memory system—for example, by extracting meaning. ([p. 298](#))

encoding specificity principle

the idea that cues and contexts specific to a particular memory will be most effective in helping us recall it. ([p. 313](#))

endocrine [EN-duh-krin] system

the body's "slow" chemical communication system; a set of glands that secrete hormones into the bloodstream. ([p. 60](#))

endorphins

[en-DOR-fins] “morphine within”—natural, opiate-like neurotransmitters linked to pain control and to pleasure. ([p. 57](#))

environment

every nongenetic influence, from prenatal nutrition to the people and things around us. ([p. 129](#))

epigenetics

“above” or “in addition to” (*epi*) genetics; the study of environmental influences on gene expression that occur without a DNA change. (pp. 134, 564)

episodic memory

explicit memory of personally experienced events; one of our two conscious memory systems (the other is *semantic memory*). ([p. 307](#))

equity

a condition in which people receive from a relationship in proportion to what they give to it. ([p. 516](#))

erectile disorder

inability to develop or maintain an erection due to insufficient bloodflow to the penis. ([p. 405](#))

estrogens

sex hormones, such as estradiol, that contribute to female sex characteristics and are secreted in greater amounts by females than by males. Estrogen levels peak during ovulation. In nonhuman mammals, this promotes sexual receptivity. ([p. 403](#))

evidence-based practice

clinical decision making that integrates the best available research with clinical expertise and patient characteristics and preferences. ([p. 629](#))

evolutionary psychology

the study of the evolution of behavior and the mind, using principles of natural selection. (pp. 10, 137)

experiment

a research method in which an investigator manipulates one or more factors (independent variables) to observe the effect on some behavior or mental process (the dependent variable). By *random assignment* of participants, the experimenter aims to control other relevant factors. ([p. 34](#))

experimental group

in an experiment, the group exposed to the treatment, that is, to one version of the independent variable. ([p. 34](#))

explicit memory

retention of facts and experiences that one can consciously know and “declare.” (Also called *declarative memory*.) ([p. 300](#))

exposure therapies

behavioral techniques, such as *systematic desensitization* and *virtual reality exposure therapy*, that treat anxieties by exposing people (in imaginary or actual situations) to the things they fear and avoid. ([p. 615](#))

external locus of control

the perception that chance or outside forces beyond our personal control determine our fate. ([p. 465](#))

extinction

the diminishing of a conditioned response; occurs in classical conditioning when an unconditioned stimulus (US) does not follow a conditioned stimulus (CS); occurs in operant conditioning when a response is no longer reinforced. ([p. 269](#))

extrasensory perception (ESP)

the controversial claim that perception can occur apart from sensory input; includes telepathy, clairvoyance, and precognition. ([p. 257](#))

extrinsic motivation

a desire to perform a behavior to receive promised rewards or avoid threatened punishment. ([p. 286](#))

facial feedback effect

the tendency of facial muscle states to trigger corresponding feelings such as fear, anger, or happiness. ([p. 439](#))

family therapy

therapy that treats people in the context of their family system. Views an individual’s unwanted behaviors as influenced by, or directed at, other family members. ([p. 622](#))

feature detectors

nerve cells in the brain that respond to specific features of the stimulus, such as shape, angle, or movement. ([p. 230](#))

feel-good, do-good phenomenon

people's tendency to be helpful when in a good mood. ([p. 443](#))

female orgasmic disorder

distress due to infrequently or never experiencing orgasm. ([p. 405](#))

fetal alcohol syndrome (FAS)

physical and cognitive abnormalities in children caused by a pregnant woman's heavy drinking. In severe cases, signs include a small, out-of-proportion head and abnormal facial features. ([p. 171](#))

fetus

the developing human organism from 9 weeks after conception to birth. ([p. 168](#))

figure-ground

the organization of the visual field into objects (the *figures*) that stand out from their surroundings (the *ground*). ([p. 232](#))

fixation

(1) in thinking, the inability to see a problem from a new perspective; an obstacle to problem solving. (2) in personality theory, according to Freud, a lingering focus of pleasure-seeking energies at an earlier psychosexual stage, in which conflicts were unresolved. (pp. 333, 531)

fixed-interval schedule

in operant conditioning, a reinforcement schedule that reinforces a response only after a specified time has elapsed. ([p. 276](#))

fixed-ratio schedule

in operant conditioning, a reinforcement schedule that reinforces a response only after a specified number of responses. ([p. 276](#))

flashbulb memory

a clear memory of an emotionally significant moment or event. ([p. 308](#))

flow

a completely involved, focused state, with diminished awareness of self and time; results from full engagement of our skills. (p. A-1)

fluid intelligence

our ability to reason speedily and abstractly; tends to decrease with age, especially during late adulthood. ([p. 372](#))

fMRI (functional MRI)

a technique for revealing bloodflow and, therefore, brain activity by comparing successive MRI scans. fMRI scans show brain function as

well as structure. ([p. 67](#))

foot-in-the-door phenomenon

the tendency for people who have first agreed to a small request to comply later with a larger request. ([p. 480](#))

formal operational stage

in Piaget's theory, the stage of cognitive development (normally beginning about age 12) during which people begin to think logically about abstract concepts. ([p. 179](#))

fovea

the central focal point in the retina, around which the eye's cones cluster. ([p. 227](#))

framing

the way an issue is posed; how an issue is framed can significantly affect decisions and judgments. ([p. 337](#))

fraternal (dizygotic) twins

develop from separate fertilized eggs. They are genetically no closer than ordinary brothers and sisters, but they share a prenatal environment. ([p. 131](#))

free association

in psychoanalysis, a method of exploring the unconscious in which the person relaxes and says whatever comes to mind, no matter how trivial or embarrassing. ([p. 528](#))

frequency

the number of complete wavelengths that pass a point in a given time (for example, per second). ([p. 242](#))

frequency theory

in hearing, the theory that the rate of nerve impulses traveling up the auditory nerve matches the frequency of a tone, thus enabling us to sense its pitch. (Also called *temporal theory*.) ([p. 245](#))

frontal lobes

the portion of the cerebral cortex lying just behind the forehead; involved in speaking and muscle movements and in making plans and judgments. ([p. 75](#))

frustration-aggression principle

the principle that frustration—the blocking of an attempt to achieve

some goal—creates anger, which can generate aggression. ([p. 507](#))

functionalism

early school of thought promoted by James and influenced by Darwin; explored how mental and behavioral processes function—how they enable the organism to adapt, survive, and flourish. ([p. 7](#))

fundamental attribution error

the tendency for observers, when analyzing others' behavior, to underestimate the impact of the situation and to overestimate the impact of personal disposition. ([p. 478](#))

gate-control theory

the theory that the spinal cord contains a neurological “gate” that blocks pain signals or allows them to pass on to the brain. The “gate” is opened by the activity of pain signals traveling up small nerve fibers and is closed by activity in larger fibers or by information coming from the brain. ([p. 248](#))

gender

in psychology, the socially influenced characteristics by which people define *boy*, *girl*, *man*, and *woman*. ([p. 152](#))

gender identity

our sense of being male, female, or some combination of the two. ([p. 161](#))

gender role

a set of expected behaviors, attitudes, and traits for males or for females. ([p. 158](#))

gender typing

the acquisition of a traditional masculine or feminine role. ([p. 161](#))

general adaptation syndrome (GAS)

Selye's concept of the body's adaptive response to stress in three phases—alarm, resistance, exhaustion. ([p. 454](#))

general intelligence (g)

according to Spearman and others, underlies all mental abilities and is therefore measured by every task on an intelligence test. ([p. 360](#))

generalization

the tendency, once a response has been conditioned, for stimuli similar to the conditioned stimulus to elicit similar responses. (In operant

conditioning, generalization occurs when responses learned in one situation occur in other, similar situations.) ([p. 269](#))

generalized anxiety disorder

an anxiety disorder in which a person is continually tense, apprehensive, and in a state of *autonomic nervous system* arousal. ([p. 573](#))

genes

the biochemical units of heredity that make up the chromosomes; segments of DNA capable of synthesizing proteins. ([p. 129](#))

genome

the complete instructions for making an organism, consisting of all the genetic material in that organism's chromosomes. ([p. 129](#))

gestalt

an organized whole. Gestalt psychologists emphasized our tendency to integrate pieces of information into meaningful wholes. ([p. 232](#))

glial cells (glia)

cells in the nervous system that support, nourish, and protect neurons; they also play a role in learning, thinking, and memory. ([p. 53](#))

glucose

the form of sugar that circulates in the blood and provides the major source of energy for body tissues. When its level is low, we feel hunger. ([p. 396](#))

grammar

in a language, a system of rules that enables us to communicate with and understand others. *Semantics* is the language's set of rules for deriving meaning from sounds, and *syntax* is its set of rules for combining words into grammatically sensible sentences. ([p. 345](#))

GRIT

Graduated and Reciprocated Initiatives in Tension-Reduction—a strategy designed to decrease international tensions. ([p. 525](#))

grit

in psychology, passion and perseverance in the pursuit of long-term goals. ([p. 422](#))

group polarization

the enhancement of a group's prevailing inclinations through discussion within the group. ([p. 494](#))

group therapy

therapy conducted with groups rather than individuals, providing benefits from group interaction. ([p. 622](#))

grouping

the perceptual tendency to organize stimuli into coherent groups. ([p. 232](#))

groupthink

the mode of thinking that occurs when the desire for harmony in a decision-making group overrides a realistic appraisal of alternatives. ([p. 494](#))

habituation

decreasing responsiveness with repeated stimulation. As infants gain familiarity with repeated exposure to a stimulus, their interest wanes and they look away sooner. ([p. 171](#))

hallucinations

false sensory experiences, such as seeing something in the absence of an external visual stimulus. ([p. 98](#))

hallucinogens

psychedelic (“mind-manifesting”) drugs, such as LSD, that distort perceptions and evoke sensory images in the absence of sensory input. ([p. 118](#))

health psychology

a subfield of psychology that provides psychology’s contribution to behavioral medicine. ([p. 456](#))

heredity

the genetic transfer of characteristics from parents to offspring. ([p. 129](#))

heritability

the proportion of variation among individuals in a group that we can attribute to genes. The heritability of a trait may vary, depending on the range of populations and environments studied. (pp. 134, 379)

heuristic

a simple thinking strategy that often allows us to make judgments and solve problems efficiently; usually speedier but also more error-prone than an *algorithm*. ([p. 331](#))

hierarchy of needs

Maslow's pyramid of human needs, beginning at the base with physiological needs that must first be satisfied before higher-level safety needs and then psychological needs become active. (pp. 393, 539)

higher-order conditioning

a procedure in which the conditioned stimulus in one conditioning experience is paired with a new neutral stimulus, creating a second (often weaker) conditioned stimulus. For example, an animal that has learned that a tone predicts food might then learn that a light predicts the tone and begin responding to the light alone. (Also called *second-order conditioning*.) ([p. 267](#))

hindsight bias

the tendency to believe, after learning an outcome, that one would have foreseen it. (Also known as the *I-knew-it-all-along phenomenon*.) ([p. 22](#))

hippocampus

a neural center located in the limbic system; helps process explicit (conscious) memories—of facts and events—for storage. (pp. 72, 307)

homeostasis

a tendency to maintain a balanced or constant internal state; the regulation of any aspect of body chemistry, such as blood glucose, around a particular level. ([p. 391](#))

hormones

chemical messengers that are manufactured by the endocrine glands, travel through the bloodstream, and affect other tissues. ([p. 60](#))

hue

the dimension of color that is determined by the wavelength of light; what we know as the color names *blue*, *green*, and so forth. ([p. 224](#))

human factors psychology

a field of psychology allied with I/O psychology that explores how people and machines interact and how machines and physical environments can be made safe and easy to use. (p. A-3)

humanistic psychology

historically significant perspective that emphasized human growth potential. ([p. 9](#))

humanistic theories

theories that view personality with a focus on the potential for healthy personal growth. ([p. 539](#))

hypnosis

a social interaction in which one person (the hypnotist) suggests to another (the subject) that certain perceptions, feelings, thoughts, or behaviors will spontaneously occur. ([p. 250](#))

hypothalamus

[hi-po-THAL-uh-muss] a neural structure lying below (*hypo*) the thalamus; it directs several maintenance activities (eating, drinking, body temperature), helps govern the endocrine system via the pituitary gland, and is linked to emotion and reward. ([p. 70](#))

hypothesis

a testable prediction, often implied by a theory. ([p. 24](#))

iconic memory

a momentary sensory memory of visual stimuli; a photographic or picture-image memory lasting no more than a few tenths of a second. ([p. 300](#))

id

a reservoir of unconscious psychic energy that, according to Freud, strives to satisfy basic sexual and aggressive drives. The id operates on the *pleasure principle*, demanding immediate gratification. ([p. 530](#))

identical (monozygotic) twins

develop from a single fertilized egg that splits in two, creating two genetically identical organisms. ([p. 131](#))

identification

the process by which, according to Freud, children incorporate their parents' values into their developing superegos. ([p. 531](#))

identity

our sense of self; according to Erikson, the adolescent's task is to solidify a sense of self by testing and integrating various roles. ([p. 196](#))

illusory correlation

perceiving a relationship where none exists, or perceiving a stronger-than-actual relationship. ([p. 31](#))

implicit memory

retention of learned skills or classically conditioned associations independent of conscious recollection. (Also called *nondeclarative memory*.) ([p. 300](#))

imprinting

the process by which certain animals form strong attachments during early life. ([p. 185](#))

inattentional blindness

failing to see visible objects when our attention is directed elsewhere. ([p. 91](#))

incentive

a positive or negative environmental stimulus that motivates behavior. ([p. 391](#))

independent variable

in an experiment, the factor that is manipulated; the variable whose effect is being studied. ([p. 35](#))

individualism

giving priority to one's own goals over group goals and defining one's identity in terms of personal attributes rather than group identifications. ([p. 148](#))

industrial-organizational (I/O) psychology

the application of psychological concepts and methods to optimizing human behavior in workplaces. (p. A-3)

informational social influence

influence resulting from one's willingness to accept others' opinions about reality. ([p. 487](#))

informed consent

giving potential participants enough information about a study to enable them to choose whether they wish to participate. ([p. 38](#))

ingroup

"us"—people with whom we share a common identity. ([p. 501](#))

ingroup bias

the tendency to favor our own group. ([p. 501](#))

inner ear

the innermost part of the ear, containing the cochlea, semicircular canals, and vestibular sacs. ([p. 243](#))

insight

a sudden realization of a problem's solution; contrasts with strategy-based solutions. ([p. 331](#))

insight therapies

therapies that aim to improve psychological functioning by increasing a person's awareness of underlying motives and defenses. ([p. 613](#))

insomnia

recurring problems in falling or staying asleep. ([p. 105](#))

instinct

a complex behavior that is rigidly patterned throughout a species and is unlearned. ([p. 391](#))

instinctive drift

the tendency of learned behavior to gradually revert to biologically predisposed patterns. ([p. 286](#))

intellectual disability

a condition of limited mental ability, indicated by an intelligence test score of 70 or below and difficulty adapting to the demands of life. (Formerly referred to as *mental retardation*.) ([p. 375](#))

intelligence

the ability to learn from experience, solve problems, and use knowledge to adapt to new situations. ([p. 360](#))

intelligence quotient (IQ)

defined originally as the ratio of mental age (*ma*) to chronological age (*ca*) multiplied by 100 (thus, $IQ = ma/ca \times 100$). On contemporary intelligence tests, the average performance for a given age is assigned a score of 100. ([p. 367](#))

intelligence test

a method for assessing an individual's mental aptitudes and comparing them with those of others, using numerical scores. ([p. 365](#))

intensity

the amount of energy in a light wave or sound wave, which influences what we perceive as brightness or loudness. Intensity is determined by the wave's amplitude (height). ([p. 224](#))

interaction

the interplay that occurs when the effect of one factor (such as environment) depends on another factor (such as heredity). ([p. 134](#))

internal locus of control

the perception that we control our own fate. ([p. 465](#))

interneurons

neurons within the brain and spinal cord; they communicate internally and process information between the sensory inputs and motor outputs. ([p. 59](#))

interpretation

in psychoanalysis, the analyst's noting supposed dream meanings, resistances, and other significant behaviors and events in order to promote insight. ([p. 611](#))

intersex

a condition present at birth due to unusual combinations of male and female chromosomes, hormones, and anatomy; possessing biological sexual characteristics of both sexes. ([p. 158](#))

intimacy

in Erikson's theory, the ability to form close, loving relationships; a primary developmental task in young adulthood. ([p. 199](#))

intrinsic motivation

a desire to perform a behavior effectively for its own sake. ([p. 286](#))

intuition

an effortless, immediate, automatic feeling or thought, as contrasted with explicit, conscious reasoning. ([p. 333](#))

James-Lange theory

the theory that our experience of emotion is our awareness of our physiological responses to an emotion-arousing stimulus. ([p. 427](#))

just-world phenomenon

the tendency for people to believe the world is just and that people therefore get what they deserve and deserve what they get. ([p. 501](#))

kinesthesia

[kin-ehs-THEE-zhuh] the system for sensing the position and movement of individual body parts. ([p. 254](#))

language

our spoken, written, or signed words and the ways we combine them to communicate meaning. ([p. 345](#))

latent content

according to Freud, the underlying meaning of a dream (as distinct from its manifest content). ([p. 108](#))

latent learning

learning that occurs but is not apparent until there is an incentive to demonstrate it. ([p. 286](#))

law of effect

Thorndike's principle that behaviors followed by favorable consequences become more likely, and that behaviors followed by unfavorable consequences become less likely. ([p. 273](#))

leadership

an individual's ability to motivate and influence others to contribute to their group's success. (p. A-9)

learned helplessness

the hopelessness and passive resignation an animal or person learns when unable to avoid repeated aversive events. ([p. 463](#))

learning

the process of acquiring through experience new and relatively enduring information or behaviors. ([p. 262](#))

lesion [LEE-zhuhn]

tissue destruction. A brain lesion is a naturally or experimentally caused destruction of brain tissue. ([p. 65](#))

levels of analysis

the differing complementary views, from biological to psychological to social-cultural, for analyzing any given phenomenon. ([p. 12](#))

limbic system

neural system (including the *amygdala*, *hypothalamus*, and *hippocampus*) located below the cerebral hemispheres; associated with emotions and drives. ([p. 70](#))

linguistic determinism

Whorf's hypothesis that language determines the way we think. ([p. 354](#))

lobotomy

a psychosurgical procedure once used to calm uncontrollably emotional or violent patients. The procedure cut the nerves connecting the frontal lobes to the emotion-controlling centers of the inner brain. ([p. 640](#))

longitudinal study

research that follows and retests the same people over time. (pp. 207, 372)

long-term memory

the relatively permanent and limitless storehouse of the memory system. Includes knowledge, skills, and experiences. ([p. 298](#))

long-term potentiation (LTP)

an increase in a cell's firing potential after brief, rapid stimulation; a neural basis for learning and memory. ([p. 311](#))

LSD

a powerful hallucinogenic drug; also known as acid (*lysergic acid diethylamide*). ([p. 120](#))

major depressive disorder

a disorder in which a person experiences, in the absence of drugs or another medical condition, two or more weeks with five or more symptoms, at least one of which must be either (1) depressed mood or (2) loss of interest or pleasure. ([p. 581](#))

mania

a hyperactive, wildly optimistic state in which dangerously poor judgment is common. ([p. 582](#))

manifest content

according to Freud, the remembered story line of a dream (as distinct from its latent, or hidden, content). ([p. 108](#))

maturation

biological growth processes that enable orderly changes in behavior, relatively uninfluenced by experience. ([p. 173](#))

mean

the arithmetic average of a distribution, obtained by adding the scores and then dividing by the number of scores. ([p. 45](#))

median

the middle score in a distribution; half the scores are above it and half are below it. ([p. 45](#))

medical model

the concept that diseases, in this case psychological disorders, have physical causes that can be *diagnosed*, *treated*, and, in most cases, *cured*, often through treatment in a *hospital*. ([p. 564](#))

medulla

[muh-DUL-uh] the base of the brainstem; controls heartbeat and

breathing. ([p. 68](#))

MEG (magnetoencephalography)

a brain-imaging technique that measures magnetic fields from the brain's natural electrical activity. ([p. 65](#))

memory

the persistence of learning over time through the encoding, storage, and retrieval of information. ([p. 297](#))

memory consolidation

the neural storage of a long-term memory. ([p. 308](#))

menarche

[meh-NAR-key] the first menstrual period. ([p. 158](#))

menopause

the time of natural cessation of menstruation; also refers to the biological changes a woman experiences as her ability to reproduce declines. ([p. 202](#))

mental age

a measure of intelligence test performance devised by Binet; the level of performance typically associated with children of a certain chronological age. Thus, a child who does as well as an average 8-year-old is said to have a mental age of 8. ([p. 367](#))

mental set

a tendency to approach a problem in one particular way, often a way that has been successful in the past. ([p. 333](#))

mere exposure effect

the phenomenon that repeated exposure to novel stimuli increases liking of them. ([p. 511](#))

meta-analysis

a procedure for statistically combining the results of many different research studies. ([p. 627](#))

methamphetamine

a powerfully addictive drug that stimulates the central nervous system, with accelerated body functions and associated energy and mood changes; over time, appears to reduce baseline dopamine levels. ([p. 118](#))

middle ear

the chamber between the eardrum and cochlea containing three tiny

bones (hammer, anvil, and stirrup) that concentrate the vibrations of the eardrum on the cochlea's oval window. ([p. 243](#))

mindfulness meditation

a reflective practice in which people attend to current experiences in a nonjudgmental and accepting manner. ([p. 472](#))

Minnesota Multiphasic Personality Inventory (MMPI)

the most widely researched and clinically used of all personality tests. Originally developed to identify emotional disorders (still considered its most appropriate use), this test is now used for many other screening purposes. ([p. 545](#))

mirror neurons

frontal lobe neurons that some scientists believe fire when we perform certain actions or observe another doing so. The brain's mirroring of another's action may enable imitation and empathy. ([p. 288](#))

mirror-image perceptions

mutual views often held by conflicting people, as when each side sees itself as ethical and peaceful and views the other side as evil and aggressive. ([p. 522](#))

misinformation effect

occurs when misleading information has corrupted one's memory of an event. ([p. 322](#))

mnemonics

[nih-MON-iks] memory aids, especially those techniques that use vivid imagery and organizational devices. ([p. 302](#))

mode

the most frequently occurring score(s) in a distribution. ([p. 45](#))

modeling

the process of observing and imitating a specific behavior. ([p. 288](#))

molecular behavior genetics

the study of how the structure and function of genes interact with our environment to influence behavior. ([p. 134](#))

molecular genetics

the subfield of biology that studies the molecular structure and function of genes. ([p. 134](#))

monocular cue

a depth cue, such as interposition or linear perspective, available to either eye alone. ([p. 234](#))

mood-congruent memory

the tendency to recall experiences that are consistent with one's current good or bad mood. ([p. 313](#))

morpheme

in a language, the smallest unit that carries meaning; may be a word or a part of a word (such as a prefix). ([p. 345](#))

motivation

a need or desire that energizes and directs behavior. ([p. 391](#))

motor (efferent) neurons

neurons that carry outgoing information from the brain and spinal cord to the muscles and glands. ([p. 59](#))

motor cortex

an area at the rear of the frontal lobes that controls voluntary movements. ([p. 75](#))

MRI (magnetic resonance imaging)

a technique that uses magnetic fields and radio waves to produce computer-generated images of soft tissue. MRI scans show brain anatomy. ([p. 67](#))

mutation

a random error in gene replication that leads to a change. ([p. 138](#))

myelin [MY-uh-lin] sheath

a fatty tissue layer segmentally encasing the axons of some neurons; enables vastly greater transmission speed as neural impulses hop from one node to the next. ([p. 53](#))

narcissism

excessive self-love and self-absorption. (pp. 421, 558)

narcolepsy

a sleep disorder characterized by uncontrollable sleep attacks. The sufferer may lapse directly into REM sleep, often at inopportune times. ([p. 105](#))

natural selection

the principle that inherited traits that better enable an organism to survive and reproduce in a particular environment will (in competition

with other trait variations) most likely be passed on to succeeding generations. (pp. 10, 137)

naturalistic observation

a descriptive technique of observing and recording behavior in naturally occurring situations without trying to manipulate and control the situation. ([p. 26](#))

nature–nurture issue

the longstanding controversy over the relative contributions that genes and experience make to the development of psychological traits and behaviors. Today's science sees traits and behaviors arising from the interaction of nature and nurture. ([p. 10](#))

near-death experience

an altered state of consciousness reported after a close brush with death (such as cardiac arrest); often similar to drug-induced hallucinations. ([p. 120](#))

negative reinforcement

increasing behaviors by stopping or reducing negative stimuli. A negative reinforcer is any stimulus that, when *removed* after a response, strengthens the response. (*Note:* Negative reinforcement is not punishment.) ([p. 275](#))

nerves

bundled axons that form neural cables connecting the central nervous system with muscles, glands, and sense organs. ([p. 59](#))

nervous system

the body's speedy, electrochemical communication network, consisting of all the nerve cells of the peripheral and central nervous systems. ([p. 59](#))

neurocognitive disorders (NCDs)

acquired (not lifelong) disorders marked by cognitive deficits; often related to Alzheimer's disease, brain injury or disease, or substance abuse. In older adults, neurocognitive disorders were formerly called *dementia*. ([p. 207](#))

neurogenesis

the formation of new neurons. ([p. 80](#))

neuron

a nerve cell; the basic building block of the nervous system. ([p. 52](#))

neurotransmitters

chemical messengers that cross the synaptic gaps between neurons. When released by the sending neuron, neurotransmitters travel across the synapse and bind to receptor sites on the receiving neuron, thereby influencing whether that neuron will generate a neural impulse. ([p. 55](#))

neutral stimulus (NS)

in classical conditioning, a stimulus that elicits no response before conditioning. ([p. 265](#))

nicotine

a stimulating and highly addictive psychoactive drug in tobacco. ([p. 116](#))

night terrors

a sleep disorder characterized by high arousal and an appearance of being terrified; unlike nightmares, night terrors occur during NREM-3 sleep, within two or three hours of falling asleep, and are seldom remembered. ([p. 105](#))

norm

an understood rule for accepted and expected behavior. Norms prescribe “proper” behavior. ([p. 148](#))

normal curve (normal distribution)

a symmetrical, bell-shaped curve that describes the distribution of many types of data; most scores fall near the mean (about 68 percent fall within one standard deviation of it) and fewer and fewer near the extremes. (pp. 45, 369)

normative social influence

influence resulting from a person’s desire to gain approval or avoid disapproval. ([p. 487](#))

obesity

defined as a body mass index (BMI) measurement of 30 or higher. (*Overweight* individuals have a BMI of 25 or higher.) ([p. 400](#))

object permanence

the awareness that things continue to exist even when not perceived. ([p. 175](#))

observational learning

learning by observing others. ([p. 288](#))

obsessive-compulsive disorder (OCD)

a disorder characterized by unwanted repetitive thoughts (obsessions), actions (compulsions), or both. ([p. 575](#))

occipital [ahk-SIP-uh-tuhl] lobes

the portion of the cerebral cortex lying at the back of the head; includes areas that receive information from the visual fields. ([p. 75](#))

Oedipus [ED-uh-puss] complex

according to Freud, a boy's sexual desires toward his mother and feelings of jealousy and hatred for the rival father. ([p. 531](#))

olfaction

the sense of smell. ([p. 252](#))

one-word stage

the stage in speech development, from about age 1 to 2, during which a child speaks mostly in single words. ([p. 347](#))

operant behavior

behavior that operates on the environment, producing consequences. ([p. 262](#))

operant chamber

in operant conditioning research, a chamber (also known as a *Skinner box*) containing a bar or key that an animal can manipulate to obtain a food or water reinforcer; attached devices record the animal's rate of bar pressing or key pecking. ([p. 273](#))

operant conditioning

a type of learning in which a behavior becomes more likely to recur if followed by a reinforcer or less likely to recur if followed by a punisher. ([p. 273](#))

operational definition

a carefully worded statement of the exact procedures (operations) used in a research study. For example, *human intelligence* may be operationally defined as what an intelligence test measures. ([p. 24](#))

opiates

opium and its derivatives, such as morphine and heroin; depress neural activity, temporarily lessening pain and anxiety. ([p. 115](#))

opponent-process theory

the theory that opposing retinal processes (red-green, yellow-blue,

white-black) enable color vision. For example, some cells are stimulated by green and inhibited by red; others are stimulated by red and inhibited by green. ([p. 229](#))

optic nerve

the nerve that carries neural impulses from the eye to the brain. ([p. 227](#))

organizational psychology

an I/O psychology subfield that examines organizational influences on worker satisfaction and productivity and facilitates organizational change. (p. A-3)

ostracism

deliberate social exclusion of individuals or groups. ([p. 418](#))

other-race effect

the tendency to recall faces of one's own race more accurately than faces of other races. Also called the *cross-race effect* and the *own-race bias*. ([p. 502](#))

outgroup

"them"—those perceived as different or apart from our ingroup. ([p. 501](#))

overconfidence

the tendency to be more confident than correct—to overestimate the accuracy of our beliefs and judgments. ([p. 334](#))

panic disorder

an anxiety disorder marked by unpredictable, minutes-long episodes of intense dread in which a person may experience terror and accompanying chest pain, choking, or other frightening sensations; often followed by worry over a possible next attack. ([p. 573](#))

parallel processing

processing many aspects of a problem simultaneously; the brain's natural mode of information processing for many functions. (pp. 94, 230, 298)

paraphilias

sexual arousal from fantasies, behaviors, or urges involving nonhuman objects, the suffering of self or others, and/or nonconsenting persons. ([p. 405](#))

parapsychology

the study of paranormal phenomena, including ESP and psychokinesis.

([p. 257](#))

parasympathetic nervous system

the division of the autonomic nervous system that calms the body, conserving its energy. ([p. 60](#))

parietal [puh-RYE-uh-tuhl] lobes

the portion of the cerebral cortex lying at the top of the head and toward the rear; receives sensory input for touch and body position. ([p. 75](#))

partial (intermittent) reinforcement schedule

reinforcing a response only part of the time; results in slower acquisition of a response but much greater resistance to extinction than does continuous reinforcement. ([p. 276](#))

passionate love

an aroused state of intense positive absorption in another, usually present at the beginning of a romantic relationship. ([p. 515](#))

perception

the process of organizing and interpreting sensory information, enabling us to recognize meaningful objects and events. ([p. 214](#))

perceptual adaptation

the ability to adjust to changed sensory input, including an artificially displaced or even inverted visual field. ([p. 239](#))

perceptual constancy

perceiving objects as unchanging (having consistent color, brightness, shape, and size) even as illumination and retinal images change. ([p. 236](#))

perceptual set

a mental predisposition to perceive one thing and not another. ([p. 220](#))

peripheral nervous system (PNS)

the sensory and motor neurons that connect the central nervous system (CNS) to the rest of the body. ([p. 59](#))

peripheral route persuasion

occurs when people are influenced by incidental cues, such as a speaker's attractiveness. ([p. 480](#))

personal control

our sense of controlling our environment rather than feeling helpless. ([p. 463](#))

personality

an individual's characteristic pattern of thinking, feeling, and acting. ([p. 528](#))

personality disorders

inflexible and enduring behavior patterns that impair social functioning. ([p. 601](#))

personality inventory

a questionnaire (often with *true-false* or *agree-disagree* items) on which people respond to items designed to gauge a wide range of feelings and behaviors; used to assess selected personality traits. ([p. 544](#))

personnel psychology

an I/O psychology subfield that helps with job seeking, and with employee recruitment, selection, placement, training, appraisal, and development. (p. A-3)

PET (positron emission tomography) scan

a visual display of brain activity that detects where a radioactive form of glucose goes while the brain performs a given task. ([p. 65](#))

phi phenomenon

an illusion of movement created when two or more adjacent lights blink on and off in quick succession. ([p. 236](#))

phobia

an anxiety disorder marked by a persistent, irrational fear and avoidance of a specific object, activity, or situation. ([p. 574](#))

phoneme

in a language, the smallest distinctive sound unit. ([p. 345](#))

physiological need

a basic bodily requirement. ([p. 391](#))

pitch

a tone's experienced highness or lowness; depends on frequency. ([p. 243](#))

pituitary gland

the endocrine system's most influential gland. Under the influence of the hypothalamus, the pituitary regulates growth and controls other endocrine glands. ([p. 62](#))

place theory

in hearing, the theory that links the pitch we hear with the place where

the cochlea's membrane is stimulated. ([p. 245](#))

placebo [pluh-SEE-bo; Latin for "I shall please"] effect

experimental results caused by expectations alone; any effect on behavior caused by the administration of an inert substance or condition, which the recipient assumes is an active agent. ([p. 35](#))

plasticity

the brain's ability to change, especially during childhood, by reorganizing after damage or by building new pathways based on experience. ([p. 51](#))

polygraph

a machine used in attempts to detect lies that measures several of the physiological responses (such as perspiration, heart rate, and breathing changes) accompanying emotion. ([p. 433](#))

population

all those in a group being studied, from which samples may be drawn. (*Note: Except for national studies, this does not refer to a country's whole population.*) ([p. 29](#))

positive psychology

the scientific study of human flourishing, with the goals of discovering and promoting strengths and virtues that help individuals and communities to thrive. (pp. 12, 445)

positive reinforcement

increasing behaviors by presenting positive reinforcers. A positive reinforcer is any stimulus that, when *presented* after a response, strengthens the response. ([p. 275](#))

posthypnotic suggestion

a suggestion, made during a hypnosis session, to be carried out after the subject is no longer hypnotized; used by some clinicians to help control undesired symptoms and behaviors. ([p. 250](#))

posttraumatic growth

positive psychological changes as a result of struggling with extremely challenging circumstances and life crises. ([p. 643](#))

posttraumatic stress disorder (PTSD)

a disorder characterized by haunting memories, nightmares, hypervigilance, social withdrawal, jumpy anxiety, numbness of feeling, and/or insomnia that lingers for four weeks or more after a traumatic

experience. ([p. 576](#))

predictive validity

the success with which a test predicts the behavior it is designed to predict; it is assessed by computing the correlation between test scores and the criterion behavior. (Also called *criterion-related validity*.) ([p. 370](#))

prejudice

an unjustifiable (and usually negative) attitude toward a group and its members. Prejudice generally involves stereotyped beliefs, negative feelings, and a predisposition to discriminatory action. ([p. 497](#))

preoperational stage

in Piaget's theory, the stage (from about 2 to 6 or 7 years of age) during which a child learns to use language but does not yet comprehend the mental operations of concrete logic. ([p. 177](#))

preparedness

a biological predisposition to learn associations, such as between taste and nausea, that have survival value. ([p. 284](#))

primary reinforcer

an innately reinforcing stimulus, such as one that satisfies a biological need. ([p. 275](#))

primary sex characteristics

the body structures (ovaries, testes, and external genitalia) that make sexual reproduction possible. ([p. 157](#))

priming

the activation, often unconsciously, of certain associations, thus predisposing one's perception, memory, or response. (pp. 216, 312)

proactive interference

the forward-acting disruptive effect of older learning on the recall of *new* information. ([p. 319](#))

problem-focused coping

attempting to alleviate stress directly—by changing the stressor or the way we interact with that stressor. ([p. 463](#))

projective test

a personality test, such as the Rorschach, that provides ambiguous images designed to trigger projection of one's inner dynamics. ([p. 534](#))

prosocial behavior

positive, constructive, helpful behavior. The opposite of antisocial behavior. ([p. 291](#))

prototype

a mental image or best example of a category. Matching new items to a prototype provides a quick and easy method for sorting items into categories (as when comparing feathered creatures to a prototypical bird, such as a robin). ([p. 331](#))

psychiatry

a branch of medicine dealing with psychological disorders; practiced by physicians who are licensed to provide medical (for example, drug) treatments as well as psychological therapy. ([p. 15](#))

psychoactive drug

a chemical substance that alters perceptions and moods. ([p. 112](#))

psychoanalysis

(1) Freud's theory of personality that attributes thoughts and actions to unconscious motives and conflicts. (2) Sigmund Freud's therapeutic technique used in treating psychological disorders. Freud believed the patient's free associations, resistances, dreams, and transferences—and the therapist's interpretations of them—released previously repressed feelings, allowing the patient to gain self-insight. (pp. 528, 611)

psychodynamic theories

theories that view personality with a focus on the unconscious and the importance of childhood experiences. ([p. 528](#))

psychodynamic therapy

therapy deriving from the psychoanalytic tradition; views individuals as responding to unconscious forces and childhood experiences, and seeks to enhance self-insight. ([p. 613](#))

psychological disorder

a syndrome marked by a clinically significant disturbance in an individual's cognition, emotion regulation, or behavior. ([p. 562](#))

psychology

the science of behavior and mental processes. ([p. 9](#))

psychoneuroimmunology

the study of how psychological, neural, and endocrine processes

together affect the immune system and resulting health. ([p. 456](#))

psychopharmacology

the study of the effects of drugs on mind and behavior. ([p. 637](#))

psychophysics

the study of relationships between the physical characteristics of stimuli, such as their intensity, and our psychological experience of them. ([p. 214](#))

psychosexual stages

the childhood stages of development (oral, anal, phallic, latency, genital) during which, according to Freud, the id's pleasure-seeking energies focus on distinct erogenous zones. ([p. 530](#))

psychosurgery

surgery that removes or destroys brain tissue in an effort to change behavior. ([p. 640](#))

psychotherapy

treatment involving psychological techniques; consists of interactions between a trained therapist and someone seeking to overcome psychological difficulties or achieve personal growth. ([p. 611](#))

psychotic disorders

a group of disorders marked by irrational ideas, distorted perceptions, and a loss of contact with reality. ([p. 593](#))

puberty

the period of sexual maturation, during which a person becomes capable of reproducing. (pp. 157, 192)

punishment

an event that tends to decrease the behavior that it follows. ([p. 278](#))

random assignment

assigning participants to experimental and control groups by chance, thus minimizing preexisting differences between the different groups. ([p. 34](#))

random sample

a sample that fairly represents a population because each member has an equal chance of inclusion. ([p. 29](#))

range

the difference between the highest and lowest scores in a distribution. ([p.](#)

[45\)](#)

recall

a measure of memory in which the person must retrieve information learned earlier, as on a fill-in-the-blank test. ([p. 297](#))

reciprocal determinism

the interacting influences of behavior, internal cognition, and environment. ([p. 551](#))

reciprocity norm

an expectation that people will help, not hurt, those who have helped them. ([p. 521](#))

recognition

a measure of memory in which the person identifies items previously learned, as on a multiple-choice test. ([p. 297](#))

reconsolidation

a process in which previously stored memories, when retrieved, are potentially altered before being stored again. ([p. 321](#))

reflex

a simple, automatic response to a sensory stimulus, such as the knee-jerk response. ([p. 60](#))

refractory period

(1) in neural processing, a brief resting pause that occurs after a neuron has fired; subsequent action potentials cannot occur until the axon returns to its resting state. (2) in human sexuality, a resting period that occurs after orgasm, during which a person cannot achieve another orgasm. (pp. 55, 405)

regression toward the mean

the tendency for extreme or unusual scores or events to fall back (regress) toward the average. ([p. 32](#))

reinforcement

in operant conditioning, any event that *strengthens* the behavior it follows. ([p. 273](#))

reinforcement schedule

a pattern that defines how often a desired response will be reinforced. ([p. 276](#))

relational aggression

an act of aggression (physical or verbal) intended to harm a person's relationship or social standing. ([p. 152](#))

relative deprivation

the perception that one is worse off relative to those with whom one compares oneself. ([p. 447](#))

relearning

a measure of memory that assesses the amount of time saved when learning material again. ([p. 297](#))

reliability

the extent to which a test yields consistent results, as assessed by the consistency of scores on two halves of the test, on alternative forms of the test, or on retesting. ([p. 369](#))

REM rebound

the tendency for REM sleep to increase following REM sleep deprivation. ([p. 110](#))

REM sleep

rapid eye movement sleep; a recurring sleep stage during which vivid dreams commonly occur. Also known as *paradoxical sleep*, because the muscles are relaxed (except for minor twitches) but other body systems are active. ([p. 96](#))

repetitive transcranial magnetic stimulation (rTMS)

the application of repeated pulses of magnetic energy to the brain; used to stimulate or suppress brain activity. ([p. 640](#))

replication

repeating the essence of a research study, usually with different participants in different situations, to see whether the basic finding can be reproduced. ([p. 24](#))

representativeness heuristic

estimating the likelihood of events in terms of how well they seem to represent, or match, particular prototypes; may lead us to ignore other relevant information. ([p. 333](#))

repression

in psychoanalytic theory, the basic defense mechanism that banishes from consciousness anxiety-arousing thoughts, feelings, and memories. (pp. 321, 531)

resilience

the personal strength that helps most people cope with stress and recover from adversity and even trauma. ([p. 643](#))

resistance

in psychoanalysis, the blocking from consciousness of anxiety-laden material. ([p. 611](#))

respondent behavior

behavior that occurs as an automatic response to some stimulus. ([p. 262](#))

reticular formation

a nerve network that travels through the brainstem into the thalamus and plays an important role in controlling arousal. ([p. 69](#))

retina

the light-sensitive inner surface of the eye, containing the receptor rods and cones plus layers of neurons that begin the processing of visual information. ([p. 224](#))

retinal disparity

a binocular cue for perceiving depth. By comparing retinal images from the two eyes, the brain computes distance—the greater the disparity (difference) between the two images, the closer the object. ([p. 234](#))

retrieval

the process of getting information out of memory storage. ([p. 298](#))

retroactive interference

the backward-acting disruptive effect of newer learning on the recall of *old* information. ([p. 319](#))

retrograde amnesia

an inability to retrieve information from one's past. ([p. 317](#))

reuptake

a neurotransmitter's reabsorption by the sending neuron. ([p. 55](#))

rods

retinal receptors that detect black, white, and gray, and are sensitive to movement; necessary for peripheral and twilight vision, when cones don't respond. ([p. 227](#))

role

a set of expectations (norms) about a social position, defining how those in the position ought to behave. (pp. 158, 480)

Rorschach inkblot test

the most widely used projective test; a set of 10 inkblots, designed by Hermann Rorschach; seeks to identify people's inner feelings by analyzing their interpretations of the blots. ([p. 534](#))

rumination

compulsive fretting; *overthinking* our problems and their causes. ([p. 587](#))

savant syndrome

a condition in which a person otherwise limited in mental ability has an exceptional specific skill, such as in computation or drawing. ([p. 360](#))

scaffold

in Vygotsky's theory, a framework that offers children temporary support as they develop higher levels of thinking. ([p. 179](#))

scapegoat theory

the theory that prejudice offers an outlet for anger by providing someone to blame. ([p. 502](#))

scatterplot

a graphed cluster of dots, each of which represents the values of two variables. The slope of the points suggests the direction of the relationship between the two variables. The amount of scatter suggests the strength of the correlation (little scatter indicates high correlation). ([p. 31](#))

schema

a concept or framework that organizes and interprets information. ([p. 175](#))

schizophrenia

a disorder characterized by delusions, hallucinations, disorganized speech, and/or diminished, inappropriate emotional expression. ([p. 593](#))

secondary sex characteristics

nonreproductive sexual traits, such as female breasts and hips, male voice quality, and body hair. ([p. 157](#))

selective attention

the focusing of conscious awareness on a particular stimulus. ([p. 91](#))

self

in contemporary psychology, assumed to be the center of personality,

the organizer of our thoughts, feelings, and actions. ([p. 555](#))

self-actualization

according to Maslow, one of the ultimate psychological needs that arises after basic physical and psychological needs are met and self-esteem is achieved; the motivation to fulfill one's potential. ([p. 539](#))

self-concept

all our thoughts and feelings about ourselves, in answer to the question, "Who am I?" (pp. 188, 541)

self-control

the ability to control impulses and delay short-term gratification for greater long-term rewards. ([p. 465](#))

self-disclosure

the act of revealing intimate aspects of oneself to others. ([p. 516](#))

self-efficacy

one's sense of competence and effectiveness. ([p. 555](#))

self-esteem

one's feelings of high or low self-worth. ([p. 555](#))

self-fulfilling prophecy

a belief that leads to its own fulfillment. ([p. 522](#))

self-serving bias

a readiness to perceive oneself favorably. ([p. 557](#))

self-transcendence

according to Maslow, the striving for identity, meaning, and purpose beyond the self. ([p. 539](#))

semantic memory

explicit memory of facts and general knowledge; one of our two conscious memory systems (the other is *episodic memory*). ([p. 307](#))

sensation

the process by which our sensory receptors and nervous system receive and represent stimulus energies from our environment. ([p. 214](#))

sensorimotor stage

in Piaget's theory, the stage (from birth to nearly 2 years of age) during which infants know the world mostly in terms of their sensory impressions and motor activities. ([p. 175](#))

sensorineural hearing loss

hearing loss caused by damage to the cochlea's receptor cells or to the auditory nerves; the most common form of hearing loss, also called *nerve deafness*. ([p. 244](#))

sensory adaptation

diminished sensitivity as a consequence of constant stimulation. ([p. 218](#))

sensory (afferent) neurons

neurons that carry incoming information from the body's tissues and sensory receptors to the brain and spinal cord. ([p. 59](#))

sensory interaction

the principle that one sense may influence another, as when the smell of food influences its taste. ([p. 255](#))

sensory memory

the immediate, very brief recording of sensory information in the memory system. ([p. 298](#))

sensory receptors

sensory nerve endings that respond to stimuli. ([p. 214](#))

sequential processing

processing one aspect of a problem at a time; generally used to process new information or to solve difficult problems. ([p. 94](#))

serial position effect

our tendency to recall best the last (*recency effect*) and first (*primacy effect*) items in a list. ([p. 313](#))

set point

the point at which your "weight thermostat" may be set. When your body falls below this weight, increased hunger and a lowered metabolic rate may combine to restore lost weight. ([p. 398](#))

sex

in psychology, the biologically influenced characteristics by which people define *male* and *female*. ([p. 152](#))

sexual dysfunction

a problem that consistently impairs sexual arousal or functioning at any point in the sexual response cycle. ([p. 405](#))

sexual orientation

an enduring sexual attraction toward members of one's own sex (homosexual orientation), the other sex (heterosexual orientation), or

both sexes (bisexual orientation). ([p. 409](#))

sexual response cycle

the four stages of sexual responding described by Masters and Johnson—excitement, plateau, orgasm, and resolution. ([p. 405](#))

shallow processing

encoding on a basic level, based on the structure or appearance of words. ([p. 305](#))

shaping

an operant conditioning procedure in which reinforcers guide behavior toward closer and closer approximations of the desired behavior. ([p. 275](#))

short-term memory

activated memory that holds a few items briefly, such as digits of a phone number while calling, before the information is stored or forgotten. ([p. 298](#))

signal detection theory

a theory predicting how and when we detect the presence of a faint stimulus (*signal*) amid background stimulation (*noise*). Assumes there is no single absolute threshold and that detection depends partly on a person's experience, expectations, motivation, and alertness. ([p. 216](#))

sleep

a periodic, natural loss of consciousness—as distinct from unconsciousness resulting from a coma, general anesthesia, or hibernation. (Adapted from Dement, 1999.) ([p. 95](#))

sleep apnea

a sleep disorder characterized by temporary cessations of breathing during sleep and repeated momentary awakenings. ([p. 105](#))

social clock

the culturally preferred timing of social events such as marriage, parenthood, and retirement. ([p. 208](#))

social exchange theory

the theory that our social behavior is an exchange process, the aim of which is to maximize benefits and minimize costs. ([p. 521](#))

social facilitation

improved performance on simple or well-learned tasks in the presence

of others. ([p. 491](#))

social identity

the “we” aspect of our self-concept; the part of our answer to “Who am I?” that comes from our group memberships. ([p. 196](#))

social leadership

group-oriented leadership that builds teamwork, mediates conflict, and offers support. (p. A-10)

social learning theory

the theory that we learn social behavior by observing and imitating and by being rewarded or punished. ([p. 161](#))

social loafing

the tendency for people in a group to exert less effort when pooling their efforts toward attaining a common goal than when individually accountable. ([p. 493](#))

social psychology

the scientific study of how we think about, influence, and relate to one another. ([p. 478](#))

social script

a culturally modeled guide for how to act in various situations. (pp. 143, 507)

social trap

a situation in which the conflicting parties, by each pursuing their self-interest rather than the good of the group, become caught in mutually destructive behavior. ([p. 521](#))

social-cognitive perspective

views behavior as influenced by the interaction between people’s traits (including their thinking) and their social context. ([p. 551](#))

social-responsibility norm

an expectation that people will help those needing their help. ([p. 521](#))

somatic nervous system

the division of the peripheral nervous system that controls the body’s skeletal muscles. Also called the *skeletal nervous system*. ([p. 59](#))

somatosensory cortex

an area at the front of the parietal lobes that registers and processes body touch and movement sensations. ([p. 79](#))

source amnesia

faulty memory for how, when, or where information was learned or imagined. (Also called *source misattribution*.) Source amnesia, along with the misinformation effect, is at the heart of many false memories. ([p. 322](#))

spacing effect

the tendency for distributed study or practice to yield better long-term retention than is achieved through massed study or practice. ([p. 302](#))

spermarche

[sper-MAR-key] the first ejaculation. ([p. 158](#))

split brain

a condition resulting from surgery that isolates the brain's two hemispheres by cutting the fibers (mainly those of the corpus callosum) connecting them. ([p. 82](#))

spontaneous recovery

the reappearance, after a pause, of an extinguished conditioned response. ([p. 269](#))

spotlight effect

overestimating others' noticing and evaluating our appearance, performance, and blunders (as if we presume a spotlight shines on us). ([p. 555](#))

SQ3R

a study method incorporating five steps: Survey, Question, Read, Retrieve, Review. ([p. 18](#))

standard deviation

a computed measure of how much scores vary around the mean score. ([p. 45](#))

standardization

defining uniform testing procedures and meaningful scores by comparison with the performance of a pretested group. ([p. 369](#))

Stanford-Binet

the widely used American revision (by Terman at Stanford University) of Binet's original intelligence test. ([p. 367](#))

statistical significance

a statistical statement of how likely it is that an obtained result occurred

by chance. ([p. 46](#))

stereotype

a generalized (sometimes accurate but often overgeneralized) belief about a group of people. ([p. 497](#))

stereotype threat

a self-confirming concern that one will be evaluated based on a negative stereotype. ([p. 386](#))

stimulants

drugs (such as caffeine, nicotine, and the more powerful cocaine, amphetamines, methamphetamine, and Ecstasy) that excite neural activity and speed up body functions. ([p. 116](#))

stimulus

any event or situation that evokes a response. ([p. 262](#))

storage

the process of retaining encoded information over time. ([p. 298](#))

stranger anxiety

the fear of strangers that infants commonly display, beginning by about 8 months of age. ([p. 183](#))

stress

the process by which we perceive and respond to certain events, called *stressors*, that we appraise as threatening or challenging. ([p. 451](#))

structuralism

early school of thought promoted by Wundt and Titchener; used introspection to reveal the structure of the human mind. ([p. 7](#))

structured interview

an interview process that asks the same job-relevant questions of all applicants, each of whom is rated on established scales. (p. A-6)

subjective well-being

self-perceived happiness or satisfaction with life. Used along with measures of objective well-being (for example, physical and economic indicators) to evaluate people's quality of life. ([p. 445](#))

subliminal

below one's absolute threshold for conscious awareness. ([p. 216](#))

substance use disorder

a disorder characterized by continued substance craving and use despite

significant life disruption and/or physical risk. ([p. 112](#))

superego

the part of personality that, according to Freud, represents internalized ideals and provides standards for judgment (the conscience) and for future aspirations. ([p. 530](#))

superordinate goals

shared goals that override differences among people and require their cooperation. ([p. 522](#))

suprachiasmatic nucleus (SCN)

a pair of cell clusters in the hypothalamus that controls circadian rhythm. In response to light, the SCN causes the pineal gland to adjust melatonin production, thus modifying our feelings of sleepiness. ([p. 100](#))

survey

a descriptive technique for obtaining the self-reported attitudes or behaviors of a particular group, usually by questioning a representative, *random sample* of the group. ([p. 29](#))

sympathetic nervous system

the division of the autonomic nervous system that arouses the body, mobilizing its energy. ([p. 59](#))

synapse [SIN-aps]

the junction between the axon tip of the sending neuron and the dendrite or cell body of the receiving neuron. The tiny gap at this junction is called the *synaptic gap* or *synaptic cleft*. ([p. 55](#))

systematic desensitization

a type of exposure therapy that associates a pleasant relaxed state with gradually increasing anxiety-triggering stimuli. Commonly used to treat phobias. ([p. 617](#))

task leadership

goal-oriented leadership that sets standards, organizes work, and focuses attention on goals. (p. A-10)

telegraphic speech

early speech stage in which a child speaks like a telegram—“go car”—using mostly nouns and verbs. ([p. 347](#))

temperament

a person's characteristic emotional reactivity and intensity. ([p. 133](#))

temporal lobes

the portion of the cerebral cortex lying roughly above the ears; includes the auditory areas, each receiving information primarily from the opposite ear. ([p. 75](#))

tend and befriend

under stress, people (especially women) often provide support to others (tend) and bond with and seek support from others (befriend). ([p. 454](#))

teratogens

(literally, “monster makers”) agents, such as chemicals and viruses, that can reach the embryo or fetus during prenatal development and cause harm. ([p. 171](#))

terror-management theory

a theory of death-related anxiety; explores people's emotional and behavioral responses to reminders of their impending death. ([p. 537](#))

testing effect

enhanced memory after retrieving, rather than simply rereading, information. Also referred to as a *retrieval practice effect* or *test-enhanced learning*. (pp. 17, 302)

testosterone

the most important male sex hormone. Both males and females have it, but the additional testosterone in males stimulates the growth of the male sex organs during the fetal period, and the development of the male sex characteristics during puberty. (pp. 157, 403)

thalamus [THAL-uh-muss]

the brain's sensory control center, located on top of the brainstem; it directs messages to the sensory receiving areas in the cortex and transmits replies to the cerebellum and medulla. ([p. 69](#))

THC

the major active ingredient in marijuana; triggers a variety of effects, including mild hallucinations. ([p. 120](#))

Thematic Apperception Test (TAT)

a projective test in which people express their inner feelings and interests through the stories they make up about ambiguous scenes. ([p. 534](#))

theory

an explanation using an integrated set of principles that organizes observations and predicts behaviors or events. ([p. 24](#))

theory of mind

people's ideas about their own and others' mental states—about their feelings, perceptions, and thoughts, and the behaviors these might predict. ([p. 179](#))

therapeutic alliance

a bond of trust and mutual understanding between a therapist and client, who work together constructively to overcome the client's problem. ([p. 631](#))

threshold

the level of stimulation required to trigger a neural impulse. ([p. 55](#))

token economy

an operant conditioning procedure in which people earn a token for exhibiting a desired behavior and can later exchange the tokens for privileges or treats. ([p. 618](#))

tolerance

the diminishing effect with regular use of the same dose of a drug, requiring the user to take larger and larger doses before experiencing the drug's effect. ([p. 112](#))

top-down processing

information processing guided by higher-level mental processes, as when we construct perceptions drawing on our experience and expectations. ([p. 214](#))

trait

a characteristic pattern of behavior or a disposition to feel and act in certain ways, as assessed by self-report inventories and peer reports. ([p. 542](#))

transduction

conversion of one form of energy into another. In sensation, the transforming of stimulus energies, such as sights, sounds, and smells, into neural impulses our brain can interpret. ([p. 214](#))

transference

in psychoanalysis, the patient's transfer to the analyst of emotions linked

with other relationships (such as love or hatred for a parent). ([p. 611](#))

transgender

an umbrella term describing people whose gender identity or expression differs from that associated with their birth-designated sex. ([p. 161](#))

two-factor theory

the Schachter-Singer theory that to experience emotion one must (1) be physically aroused and (2) cognitively label the arousal. ([p. 429](#))

two-word stage

beginning about age 2, the stage in speech development during which a child speaks mostly in two-word statements. ([p. 347](#))

Type A

Friedman and Rosenman's term for competitive, hard-driving, impatient, verbally aggressive, and anger-prone people. ([p. 458](#))

Type B

Friedman and Rosenman's term for easygoing, relaxed people. ([p. 458](#))

unconditional positive regard

a caring, accepting, nonjudgmental attitude, which Carl Rogers believed would help people develop self-awareness and self-acceptance. (pp. 539, 615)

unconditioned response (UR)

in classical conditioning, an unlearned, naturally occurring response (such as salivation) to an unconditioned stimulus (US) (such as food in the mouth). ([p. 267](#))

unconditioned stimulus (US)

in classical conditioning, a stimulus that unconditionally—naturally and automatically—triggers an unconditioned response (UR). ([p. 267](#))

unconscious

according to Freud, a reservoir of mostly unacceptable thoughts, wishes, feelings, and memories. According to contemporary psychologists, information processing of which we are unaware. ([p. 528](#))

validity

the extent to which a test measures or predicts what it is supposed to. (See also [content validity](#) and [predictive validity](#).) ([p. 370](#))

variable

anything that can vary and is feasible and ethical to measure. ([p. 31](#))

variable-interval schedule

in operant conditioning, a reinforcement schedule that reinforces a response at unpredictable time intervals. ([p. 276](#))

variable-ratio schedule

in operant conditioning, a reinforcement schedule that reinforces a response after an unpredictable number of responses. ([p. 276](#))

vestibular sense

the sense of body movement and position, including the sense of balance. ([p. 254](#))

virtual reality exposure therapy

a counterconditioning technique that treats anxiety through creative electronic simulations in which people can safely face their greatest fears, such as airplane flying, spiders, or public speaking. ([p. 617](#))

visual cliff

a laboratory device for testing depth perception in infants and young animals. ([p. 234](#))

wavelength

the distance from the peak of one light or sound wave to the peak of the next. Electromagnetic wavelengths vary from the short blips of gamma rays to the long pulses of radio transmission. ([p. 224](#))

Weber's law

the principle that, to be perceived as different, two stimuli must differ by a constant minimum percentage (rather than a constant amount). ([p. 217](#))

Wechsler Adult Intelligence Scale (WAIS)

the WAIS and its companion versions for children are the most widely used intelligence tests; they contain verbal and performance (nonverbal) subtests. ([p. 367](#))

Wernicke's area

a brain area involved in language comprehension and expression; usually in the left temporal lobe. ([p. 351](#))

withdrawal

the discomfort and distress that follow discontinuing an addictive drug or behavior. ([p. 112](#))

working memory

a newer understanding of short-term memory that adds conscious, active

processing of incoming auditory and visual information, and of information retrieved from long-term memory. ([p. 298](#))

X chromosome

the sex chromosome found in both males and females. Females typically have two X chromosomes; males typically have one. An X chromosome from each parent produces a female child. ([p. 157](#))

Y chromosome

the sex chromosome typically found only in males. When paired with an X chromosome from the mother, it produces a male child. ([p. 157](#))

Yerkes-Dodson law

the principle that performance increases with arousal only up to a point, beyond which performance decreases. ([p. 393](#))

Young-Helmholtz trichromatic (three-color) theory

the theory that the retina contains three different types of color receptors—one most sensitive to red, one to green, one to blue—which, when stimulated in combination, can produce the perception of any color. ([p. 229](#))

zygote

the fertilized egg; it enters a 2-week period of rapid cell division and develops into an embryo. ([p. 168](#))
